INTERNATIONAL MILITARY MEDICAL STATISTICS FOR THE YEAR 1916.

These tables are those agreed upon at the International Commissic for the Unification of the Medical Statistics of Armies, held at Bud: pest in 1894: at Madrid in 1903; and modified by the last meeting, he at Berlin in 1907. They are calculated for the United States Arm proper (white and colored), and include enlisted men only. Disp sitions include cases remaining from last year. Deaths incluc suicides and accidents. Days lost include those lost this year b cases remaining from last year.

Table I shows in absolute numbers, by divisions, the mean strengt of the command, the admissions to quarters, to hospital, and tot admissions, the disposition of the sick, total, and the number returne to duty, died, and otherwise disposed of, and the total number days' sickness.

Table II gives the same data in ratios per 1,000 and also shows tl days lost per soldier and per admission.

Table III shows, by arms of service, the mean strength, the total dmissions, and those admitted to hospital only, the total dispositions, and the number of those returned to duty and the number that ied.

Table IV is omitted in the series.

Table V shows for each of the larger garrisons the mean strength, lmissions to hospital, total admissions, and the deaths.

Table VI shows for each of the 38 diseases or disease groups agreed pon by the international commission the number remaining under eatment at the commencement and close of the current year, the lmissions and dispositions for the year, the total sick days, and the verage number of days per case.

Table VII shows the admissions by arms of service for the diseases ıd disease groups referred to in Table VI.

Table VIII is omitted in the series.

Table IX shows deaths by rank, by length of service, and by age.

Table X shows the same data as Table IX for discharges for physical isability.

INTERNATIONAL TABLE I.—*Movement of sick by Army corps (departments).*

ABSOLUTE NUMBERS (ENLISTED MEN)).

Very respectfully,

W. C. GORGAS,
Surgeon General.

The SECRETARY OF WAR.

VITAL STATISTICS INDEX.

The following tables show in detail most of the statistical dat upon which the statements in this report are based:

66. Surgical operations performed on American troops.

67. Numerical view of the effect of disease and injury on United States troo serving at home and abroad in the year 1915, compared with the corresponding da for the year 1914, by races.

68. Admissions to sick report, discharges and deaths in the Army, with ratios p 1,000 of mean strength, in which all available data for the decade ending Decemb 31, 1914, are placed in comparison with the year 1915.

68½. Admissions to sick report, discharges, deaths, and noneffectiveness, wi ratios per 1,000 of mean strength, for the Army; separately for officers, total enlist (including American, Porto Rican, and Philippine troops), and grand total, ye 1915.

69. Admissions to sick report, discharges, deaths, and noneffectiveness, wi ratios per 1,000 of mean strength, for the Army; officers, total enlisted Americ troops, and grand total, year 1915.

70. Admissions to sick report, discharges, deaths, and noneffectiveness, with rati per 1,000 of mean strength, for the Army, American troops, total enlisted, and sep rately for white and colored.

70½. Admissions to sick report, discharges, deaths, and noneffectiveness, wi ratios per 1,000 of mean strength, for the United States, continental (excluding Alask separately for officers and enlisted men, and the grand total.

71. Admissions to sick report, discharges, deaths, and noneffectiveness, with rati per 1,000 of mean strength, for the year 1915, United States, continental (excludi Alaska), total enlisted, white and colored; and separately for the white and color troops (enlisted) serving therein.

71½. Admissions to sick report, discharges, deaths, and noneffectiveness, with rat per 1,000 of mean strength, for the officers separately; total enlisted, including Phil pine Scouts; and total officers and enlisted men, including Philippine Scouts, servi in the Philippine Islands, for the year 1915.

72. Admissions to sick report, discharges, deaths, and noneffectiveness, with rat per 1,000 of mean strength, for total American troops, enlisted men, white and color and separately for white and colored American enlisted men serving in the Phil pine Islands, year 1915.

73. Admissions to sick report, discharges, deaths, and noneffectiveness, with rat per 1,000 of mean strength, for American troops serving in Alaska, Panama Ca Zone, and China, officers and enlisted men, for the year 1915.

74. Admissions to sick report, discharges, deaths, and noneffectiveness, with rat per 1,000 of mean strength, for American troops serving in Hawaii, 1915, separat or officers, enlisted men, white, colored, and total.

75. Admissions to sick report, discharges, deaths, and noneffectiveness, with rat per 1,000 of mean strength, for American troops serving on Army transports, offic and native troops serving in Porto Rico, and for the Philippine Scouts, for year 19

76. Admissions to sick report, discharges, deaths, and noneffectiveness expres in ratios per 1,000 of mean strength, for American troops (enlisted men) serving duty at home stations placed in comparison with the same data for those serving distant stations, year 1915.

77. (Foreign table not used this year.)

78. (Foreign table not used this year.)

79. Showing the most important diseases, by departments, in the United Sta (continental, excluding Alaska), officers and enlisted men, year 1915.

80. Comparative figures, Army, enlisted American troops, 1911–1915.

81. Admissions and cases compared, 1904–1911, inclusive.

Letter of transmittal 15
Health of the Army. A comparative study, 1820–1917: 21
I. The health of the Army, now and formerly 23
1. Death rates since 1820 23
2. Rates of admission to sick report since 1820 26
3. Rates of discharge because of disability since 1820 27
4. Noneffective rates since 1870 28
5. Monthly variations in the health of the Army in 1917 29
II. The health of the Army analyzed 32
1. The health of the army by race 32
2. The health of the army in different places 35
a. United States Hawaii and the Philippine Islands 35
b. Continental United States 36
3. The health of the Army classified by age 37
4. The health of the Army classified by length of service 41
5. The health of the Army classified by officers and men 42
III. The causes of death 42
1. General 42
2. The most important causes of death 44
Mobilization of the Army 46
I. The physical examinations at local and medical advisory boards 48
II. Mobilization camps 51
1. Camp Devens, Mass 52
2. Camp Upton, N. Y 54
3. Camp Dix, N. J 56
4. Camp Meade, Md 58
5. Camp Lee, Va 59
6. Camp Taylor, Ky 62
7. Camp Sherman, Ohio 63
8. Camp Custer, Mich 67
9. Camp Grant, Ill 69
10. Camp Dodge, Iowa 71
11. Camp Funston, Kans 73
12. Camp Lewis, Wash 76
13. Camp Jackson, S. C 78
14. Camp Gordon, Ga 81
15. Camp Pike, Ark 83
16. Camp Travis, Tex 86
17. Camp Wadsworth, S. C 88
18. Camp Sevier, S. C 90
19. Camp Hancock, Ga 92
20. Camp Wheeler, Ga 93
21. Camp Sheridan, Ala 96
22. Camp McClellan, Ala 98
23. Camp Shelby, Miss 99
24. Camp Beauregard, La 101
25. Camp Doniphan, Okla 105
26. Camp MacArthur, Tex 107
27. Camp Logan, Tex 108
28. Camp Bowie, Tex 109
29. Camp Cody, N. Mex 113
30. Camp Kearney, Cal 114
III. Base hospitals and special services 116
Health of the Army by countries 140
I. Officers 140
1. Admissions 140
2. Deaths 140
3. Noneffective rates 140

D. Health of the Army by countries—Continued.

II. United States enlisted men
1. Admissions
2. Deaths
3. Discharges
4. Noneffective rates
III. American Expeditionary Forces
1. Admissions
2. Deaths
3. Discharges
4. Noneffective rates
IV. American troops serving in Philippine Islands, Hawaii, Panama, Mexico, China, and on transports
1. Admissions
2. Deaths
3. Discharges
4. Noneffective rates
V. Native troops: Porto Ricans and Philippine scouts
1. Porto Ricans
2. Philippine scouts
E. Special diseases in the Army
I. Measles
1. General
2. Measles in respect to race
3. Measles by camps
4. Complications of measles
5. Epidemilogical methods
II. The pneumonias
1. Primary lobar pneumonia
a. General
b. Lobar pneumonia, by state of nativity
c. Lobar pneumonia, by camps
2. Primary broncho-pneumonia
3. Measles as primary to pneumonia
III. Venereal diseases
1. Classification
2. Summary of statistics
3. Critique of statistics
4. Is venereal disease more or less frequent in the Army than in civil life?
5. Comparison of frequency of gonorrhea in white and in colored troops
6. Relative amount of venereal disease in the three armies
7. Relative frequency of venereal diseases in rural vs. urban recruits
8. How does the rate for gonococcus infection in the Army in Europe compare with that in America?
IV. Cerebrospinal meningitis
1. Simple meningitis
2. Epidemic cerebrospinal meningitis
3. Epidemic meningitis by camps
V. Scarlet fever
VI. Tuberculosis
VII. Mumps
VIII. Typhoid fever
1. General
2. Vaccination against typhoid and the paratyphoid fevers
3. Reports from departments
4. Hawaii
IX. The fruits of preventative medicine
F. Fractures and operations
I. Simple fractures
II. Compound fractures
III. Comminuted fractures
IV. Operations

Page.
. Activities of the Medical Department 265
I. Chief Surgeon's Office American Expeditionary Forces 265
1. General remarks 265
2. Hospitalization 266
3. Epidemiology 266

TABLES.

1. Years of sickness, deaths from sickness, and years of sickness to each death in the United States Army (American troops), annually, 1907–1917 22
2. Death rate in United States Army (American troops) per 1,000 mean strength, by decennial periods, 1820–1909, and single years, 1910–1917 23
3. Death rate in United States Army (American troops) per 1,000 mean strength, compared with death rate of Swedes, 1821–1910 25
4. Rate of admission to sick report in United States Army (American troops) per 1,000 mean strength, by decennial periods, 1820–1909, and single years, 1910–1917 27
5. Rate of discharge for permanent disability in United States Army (American troops) per 1,000 mean strength, by decennial periods, 1820–1909, and single years, 1910–1917 28
6. Noneffective rate in United States Army (American troops) per 1,000 mean strength, by decennial periods, 1870–1909, and single years, 1910–1917 29
7. Death rate in Army (officers and enlisted men, all stations), by months 30
8. Death rate per 1,000 mean strength in United States Army (enlisted men), classified by race, for the decade 1908–1917 34
9. Admissions to sick report in United States Army (enlisted men), classified by race, for the decade 1908–1917 34
10. Rate of discharge for permanent disability in United States Army (enlisted men), classified by race, for the decade 1908–1917 35
11. Death rate in Army (enlisted men), by location of command, for States in which 50 or more deaths occurred 36
12. Death rate in United States Army (enlisted men), by location of command, for groups of States, 1917 37
13. Health of United States Army (American troops), classified by age, 1905–1913, with ratios per 1,000 mean strength 39
14. Health of United States Army (American troops), classified by length of service (1905–1913) 41
15. Death rate of United States Army (American troops) from diseases and from external causes (1907–1917) 43
16. Number and per cent of deaths from the main diseases, United States Army (enlisted men), 1916 and 1917 44
17. Rejections and physical examinations at camps 51
18. Admissions and deaths, infectious diseases, Camp Devens 53
19. Admissions and deaths, infectious diseases, Camp Upton 55
20. Admissions and deaths, infectious diseases, Camp Dix 57
21. Admissions and deaths, infectious diseases, Camp Meade 59
22. Admissions and deaths, infectious diseases, Camp Lee 61
23. Admissions and deaths, infectious diseases, Camp Taylor 63
24. Admissions and deaths, infectious diseases, Camp Sherman 65
25. Admissions and deaths, infectious diseases, Camp Custer 68
26. Admissions and deaths, infectious diseases, Camp Grant 70

29. Admissions and deaths, infectious diseases, Camp Lewis 77
30. Admissions and deaths, infectious diseases, Camp Jackson 79
31. Admissions and deaths, infectious diseases, Camp Gordon 82
32. Admissions and deaths, infectious diseases, Camp Pike 84
33. Admissions and deaths, infectious diseases, Camp Travis 87
34. Admissions and deaths, infectious diseases, Camp Wadsworth 90
35. Admissions and deaths, infectious diseases, Camp Sevier 91
36. Admissions and deaths, infectious diseases, Camp Hancock 93
37. Admissions and deaths, infectious diseases, Camp Wheeler 94
38. Admissions and deaths, infectious diseases, Camp Sheridan 97
39. Admissions and deaths, infectious diseases, Camp McClellen 99
40. Admissions and deaths, infectious diseases, Camp Shelby 100
41. Admissions and deaths, infectious diseases, Camp Beauregard 102
42. Admissions and deaths, infectious diseases, Camp Doniphan 106
43. Admissions and deaths, infectious diseases, Camp MacArthur 107
44. Admissions and deaths, infectious diseases, Camp Logan 109
45. Admissions and deaths, infectious diseases, Camp Bowie 110
46. Admissions and deaths, infectious diseases, Camp Cody 114
47. Admissions and deaths, infectious diseases, Camp Kearney 115
48. Total admissions from September to December, 1917, inclusive, from selected infectious diseases, by camps, United States enlisted men (absolute numbers) 118
49. Total admissions from September to December, 1917, inclusive, from selected infectious diseases, by camps, United States enlisted men (ratios per 1,000 mean strength) 119
50. Total deaths from September to December, 1917, inclusive, from selected infectious diseases, by camps, United States enlisted men (absolute numbers) 120
51. Total deaths from September to December, 1917, inclusive, from selected infectious diseases, by camps, United States enlisted men (ratios per 1,000 mean strength) 121
52. Admissions, by camps and months, 1917, for selected infectious diseases, United States enlisted men 122
53. Deaths, by camps and by months, 1917, for selected infectious diseases, United States enlisted men 123
54. Total admissions, deaths, and case mortality in September to December, 1917, inclusive, from selected infectious diseases, by camps, United States enlisted men 124
55. Admissions, deaths, and case mortality for selected infectious diseases, by camps, United States enlisted men, 1917 125
56. Admissions from selected infectious diseases, by State of occurrence (excluding camps), enlisted men in United States, 1917 126
57. Ratios per 1,000 mean strength, of admissions from selected infectious diseases, by State of occurrence (excluding camps), enlisted men in United States, 1917 128
58. Absolute numbers and ratio for totals, deaths, 1917, from selected infectious diseases, by State of occurrence (excluding camps), United States enlisted men 130
59. Admissions, deaths, and case mortality for selected infectious diseases, by State of occurrence (excluding camps), United States enlisted men, 1917 132
60. Absolute numbers, admissions from selected infectious diseases, United States enlisted men, 1917, by nativity 134
61. Deaths from selected infectious diseases, United States enlisted men, 1917, by nativity 136
62. Admissions, deaths, and case mortality for selected infectious diseases, by nativity, United States enlisted men, 1917 128
63. Admissions for Army, 1917, at home and abroad, selected diseases 150
64. Discharges for Army, 1917, at home and abroad, selected diseases 153
65. Deaths for Army, 1917, at home and abroad, selected diseases 154
66. Admissions, discharges, deaths, noneffective rates from disease, enlisted men in United States and other countries, for years 1917 and 1916 155
67. Admissions, officers (total), 1917, diseases 155
68. Deaths, officers (total), 1917, diseases 155
69. Discharges, officers (total), 1917, diseases 156

Page.
70. Noneffective total days, officers (total), 1917, diseases 156
71. Admissions, enlisted men, United States, 1917, diseases 157
72. Deaths, enlisted men, United States, 1917, diseases 157
73. Discharges, enlisted men, United States, 1917, diseases 158
74. Noneffective (total days) United States enlisted men, 1917, diseases 158
75. Admissions and deaths, enlisted men in United States, for selected infectious diseases for the years 1917 and 1916 159
76. Admissions, enlisted men in Europe, 1917, diseases 160
77. Deaths, enlisted men in Europe, 1917, diseases 160
78. Discharges, enlisted men in Europe, 1917, diseases 161
79. Noneffective. Total days, enlisted men in Europe, 1917, diseases 161
80. Admissions, 1917, from disease, United States enlisted men and native troops in Panama, Philippines, Mexico, Hawaii, Porto Rico, transports, China 162
81. Deaths, 1917, from disease, United States enlisted men and native troops in Panama, Philippines, Mexico, Hawaii, Porto Rico, transports, China. 162
82. Discharges, 1917, from disease, United States enlisted men and native troops in Panama, Philippines, Mexico, Hawaii, Porto Rico, transports, China 163
83. Noneffective, total days, 1917, from disease, United States enlisted men and native troops in Panama, Philippines, Mexico, Hawaii, Porto Rico, transports, China 163
84. Comparative distributions of deaths from measles, by age groups, in urban and rural States 166
85. Comparative frequency of deaths, from measles in densely and sparsely populated States and cities, males; United States census, mortality statistics, 1915 168
86. Measles, civil life; proportion of each State that is urban or rural in relation to incidence of deaths from measles and average age at death from measles 168
87. Admissions, measles, by color and complications 169
88. Complications of measles 173
89. Measles, complications, enlisted men in United States, 1917 173
90. Complications with fatal cases of measles 175
91. Pneumonias, primary and secondary 176
92. Lobar pneumonia, by months 177
93. Primary lobar pneumonia, complications 189
94. Complications with fatal cases of lobar pneumonia 190
95. Primary broncho-pneumonia, complications 190
96. Complications with fatal cases of broncho-pneumonia 191
97. Gonorrhea, by increments 198
98. Gonorrhea, by increments, by camps 199
99. Gonorrhea, by increments, by camps, by months 200
100. Admissions, gonorrhea, by months, by race and branch 201
101. Admission for venereal disease among enlisted men in the United States, by color of men and branch of service, absolute numbers 202
102. Admissions for venereal disease among enlisted men in the United States, by color of men and branch of service, ratios per 1,000 mean strength ... 203
103. Discharges from venereal disease among enlisted men in the United States, by color of men and branch of service, absolute numbers 204
104. Discharges from venereal disease among enlisted men in the United States, by color of men and branch of service, ratios per 1,000 mean strength .. 205
105. Venereal diseases among American troops in United States, Hawaii, Philippine Islands and Panama, by color of men, for years 1913 to 1917, with ratios per 1,000 mean strength 206
106. Venereal disease among American troops in United States, Hawaii, Philippine Islands and Panama, by color, for years 1913 to 1917, with ratios per 1,000 mean strength 207
107. Admissions from venereal disease, by camps, with ratios per 1,000 mean strength, United States enlisted men, for September to December, 1917, inclusive 208
108. Admissions from venereal disease, by state of occurrence (excluding camps), with ratios per 1,000 mean strength, United States enlisted men, 1917 208
109. Number of men examined from each State and number found with venereal disease, and percentage of total men examined to number with venereal disease 209

162. Changes in Regular Medical Corps from June 30, 1917, to June 30, 1918... 388
163. Strength of Medical Reserve Corps, by months, June 30, 1917, to June 30, 1918 ... 388
164. Strength of Medical Corps, National Guard, by months, June 30, 1917, to June 30, 1918 ... 389
165. Changes in the Medical Corps, National Guard, from June 30, 1917, to June 30, 1918 ... 389
166. Strength of Medical Corps, National Army, by months, June 30, 1917, to June 30, 1918 ... 390
167. Strength of Dental Corps, by months, from June 30, 1917, to June 30, 1918 390
168. Changes in Dental Corps from June 30, 1917, to June 30, 1918 ...
169. Strength of Dental Reserve Corps, by months and grades, June 30, 1917, to June 30, 1918 ... 391
170. Strength of Dental Corps, National Guard, by months, June 30, 1917, to June 30, 1918 ... 391
171. Promotions in Dental Corps, National Guard, from June 30, 1917, to June 30, 1918 ... 392
172. Commissioned personnel of the Veterinary Corps, by months and grades, from June 30, 1917, to June 30, 1918 ... 392
173. Strength of the Sanitary Corps, by months and grades, from June 30, 1917, to June 30, 1918 ... 392 393
174. Changes in the Sanitary Corps from June 30, 1917, to June 30, 1918 ... 393
175. Number of contract surgeons, and contracts made and annulled from June 30, 1917, to June 30, 1918 ... 393
176. Officers, by grades, holding commissions in Medical Department on July 1, 1918 ... 394
177. Strength of the Army Nurse Corps, by months, June 30, 1917, to June 30, 1918 ... 395
178. Enlisted personnel of the Medical Department, by months, June 30, 1917, to June 30, 1918 ... 395
179. Strength of Sanitary Corps, by months ... 395
180. Enlisted personnel of the Veterinary Corps, by months, June 30, 1917, to June 30, 1918 ... 396
181. Annual rates per 1,000, horses and mules, communicable diseases ... 428

APPENDIX. TABLES.

I. General tables giving, for total Army, admissions, discharges, deaths, other dispositions, total days lost from disease and traumatisms, 1917, with ratios per 1,000 mean strength ... 462
II. Comparative figures, enlisted American troops, Army, 1912–1917, absolute and proportionate numbers ... 465
III. Numerical view of the effect of disease and injury on United States troops, serving at home and abroad in the year 1917, compared with corresponding data for the year 1916, by races ... 467
IV. Admissions, discharges, deaths, days lost in hospital, total days lost from disease, 1917, American troops at home and abroad, by arm of service, absolute and proportionate numbers ... 468
V. Admissions from disease, enlisted men in the United States, by months and by State of occurrence, 1917, absolute numbers ... 469
VI. Admission from disease, enlisted men in the United States, by months and by State of occurrence, 1917, proportionate numbers ... 470
VII. Discharges from disease, enlisted men United States, by months and by State of occurrence, 1917 ... 472
VIII. Deaths from disease, United States, enlisted men, by months and State of occurrence, 1917 ... 473

Page.
IX. Days lost in hospital and total days lost (noneffective) from disease and from traumatism, by countries, enlisted men, for the year 1917, with ratios per 1,000 mean strength.......... 475
X. Admissions, discharges, deaths, and total days lost from disease, enlisted men in United States, by nativity.......... 476
XI. Admissions, discharges, deaths, and total days lost from disease, enlisted men in Europe, by nativity.......... 476
XII. Admissions, discharges, deaths, and total days lost from disease, enlisted men in other countries, by nativity.......... 477
XIII. Surgical operations performed on officers and enlisted men of the Army during the calendar year 1917.......... 478
XIV. Admissions to sick report, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Absolute numbers.......... 508
XV. Admissions to sick report, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Ratios per 1,000 of mean strength.......... 536
XVI. Discharges for disability, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Absolute numbers.......... 560
XVII. Discharges for disability, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Ratios per 1,000 mean strength.......... 584
XVIII. Deaths, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Absolute numbers.......... 608
XIX. Deaths, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Ratios per 1,000 mean strength.......... 628
XX. Total days lost, total noneffective, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Absolute numbers.......... 648
XXI. Total days lost, total noneffective, total Army (including officers, American and native troops), for the year 1917, at home and abroad. Ratios per 1,000 mean strength.......... 682

INTERNATIONAL TABLES.

1. Movement of sick of Army at home and abroad, 1917, absolute numbers (enlisted men).......... 716
2. Movement of sick of Army at home and abroad, 1917, proportionate numbers (enlisted men).......... 716
3. Movement of sick, by arms of service, Army, enlisted men, American troops.......... 717
4. Movement of sick by months, 1917, American troops (enlisted men) at home, absolute numbers.......... 718
4A. Movement of sick by months, 1917, American troops (enlisted men) at home, proportionate numbers.......... 718
4B. Movement of sick by months, American troops in Philippine Islands, absolute numbers.......... 719
4C. Movement of sick by months, American troops in Philippine Islands, proportionate numbers.......... 719
5. Movement of sick in the States, enlisted men, year 1917.......... 720
6. Movement of sick according to most important diseases.......... 721
8. Admissions for selected infectious diseases by months, 1917, enlisted men in United States.......... 722
10. Discharge for disability, American troops, 1917.......... 723

CHARTS.

1. Death rate of American troops, 1820–1917.......... 24
2. Death rate of enlisted men (American troops) and male Swedes, 1821–1910. 25
3. Rates, American troops, all countries, all causes, 1908–1917.......... 31
4. Rates, American troops, all countries, disease only, 1908–1917.......... 33
5. Admissions, discharges, deaths and noneffective rates, enlisted men in United States, all causes, 1908–1917.......... 38

Page.
6. Admission, discharges, death and noneffective rate, enlisted men in United States, disease only, 1908–1917 40 47
7. Monthly strength of Army, 1917 48
8. Strength by months, Regular Army, National Guard, National Army, 1917
9. Monthly increment of Army, February to December, 1917 50
10 to 39. Figures giving weekly strength of each of large camps, September to December, 1917, and draft increments for same 52–114
40. Rates, American troops at home and abroad, disease only, 1917 141
41. Admission, discharge and death, rates for disease by months, enlisted men in United States, 1917 142
42. Discharges, enlisted men, United States, 1917, disease 144
43. Discharges, enlisted men, Europe, 1917, disease 146
44. Discharges, American troops in other countries, 1917, disease 148
45. Admission and discharge rate for 10 leading diseases for United States, Europe and other countries, American and native troops, for year, 1917 151
46. Deaths and noneffective rate for 10 leading diseases, for United States, Europe and other countries, American and native troops, for year 1917 152
47. Map of United States, showing relative density of each State 164
48. Map, showing distribution of measles by State of nativity 165
49. Correlation between admissions by nativity and urbanity of State 166
50. Philadelphia and New York City, average weekly case rates from measles, 1906–1912 167
51. Measles (total), admission and death rates, per 1,000 mean strength, by camps, United States enlisted men, September to December, inclusive, 1917 170
52. Measles, admission rates per 1,000 mean strength, by camps, United States enlisted men, September to December, inclusive, 1917 171

REPORT OF THE SURGEON GENERAL OF THE ARMY.

A. LETTER OF TRANSMISSION.

I have the honor to submit herewith the one hundred and first annual report of the Surgeon General of the Army, covering statistically the calendar year 1917 and the fiscal year ending June 30, 1918.

The period embraced by this report has been one of the most memorable in the history of our country and has witnessed the unparalleled and successful activities of the War Department and the Nation, by means of which the Army of the United States, consisting of a few hundred thousand, has been speedily increased to one of several millions, well equipped and skillfully transported overseas, to take its part with Great Britain, France, Italy, and their allies against the foes of democracy and peace.

At the time of the active entrance of the United States into the great war (Apr. 6, 1917) the Medical Department of the Army had less than a thousand trained commissioned officers and a proportionate number of enlisted men. To-day it has a larger personnel than the entire Army had two decades ago at the outbreak of the Spanish-American War, and is fully prepared in all respects to meet the professional demands of the great armies now actually engaged at the front and in training in this country and abroad.

The Medical Corps of the Army has had from the first the active patriotic and unselfish cooperation and support of the medical profession of the United States. This has made possible the organization of a medical service which, for completeness of detail, from the first-aid station on the firing line to the reconstruction hospitals at the base, has rarely, if ever, been excelled.

In inaugurating and perfecting this highly specialized and technical corps, the Medical Department, or medical profession of the United States—the terms are now practically synonymous—has been assisted in the greatest measure by many associated societies and corporations (the American Red Cross, the Y. M. C. A., the Knights of Columbus, the Young Men's Hebrew Association, and others) who have patriotically devoted their great influence to the welfare and humanitarian interests of the fighting forces. The important service being rendered by the organizations mentioned and similar ones, both at home and abroad, is one of the fine features of the war, illustrating as it does the universal interest of the people in the support and protection of the armies of the country and the determination of the Nation that nothing shall be left undone to insure the successful prosecution of this world-wide conflict.

No feature of the preparatory phase of the war has been more important than the various schools for the intensive training of candidates for commissions.

Three such schools for the training of medical officers have been in existence during the year past, at Fort Oglethorpe, Fort Riley, and Fort Benjamin Harrison. All have proved their great value in preparing the physicians direct from civil life for the varied and unaccustomed duties of the medico-military practitioner and administrator.

The courses given at these training camps have been thoroughly and systematically carried out by competent instructors and earnestly and enthusiastically followed by the student officers, who have been prompt to recognize the necessity and advantage of special instruction in the great field relating to the care and protection of troops in camp and in campaign.

The health of the Army both at home and overseas has been excellent and lower probably than in any similar body of troops in the history of warfare.

Infectious diseases—measles, scarlet fever, pneumonia, epidemic meningitis—prevailed during the winter months in the various cantonments and were, as a rule, well handled, with the minimum of mortality, considering the serious character of the diseases and the necessary circumstances of rapid mobilization.

Venereal disease has been vigorously dealt with, as heretofore, in the Army. Special legislation and earnest measures taken by civil communities adjoining camps and cantonments, under the direction of the Federal authorities, have been potent means of controlling this menace which, as often stated before, originates, with rare exceptions, entirely outside the jurisdiction of the military authorities.

The first considerable body of expeditionary troops to Europe, comprising about a division of Regulars, arrived in France in May, 1917. They were preceded by certain Medical Department units, constituting an advance force of the American Army.

Since then there has been a steady flow of men and munitions across the Atlantic, and at this time an Army of a million and a half is fighting successfully on French soil. The work of the officers and men of the Medical Department overseas, under the skilled leadership of experienced and highly efficient chief surgeons, has elicited and deserved the highest praise.

The same can be fairly said of those who have remained in the United States performing faithfully and well the all-important tasks assigned to them of organization, supply, and training.

Speaking more in detail, the mean strength of the Army at the beginning of 1917 was only 217,272 officers and men, all branches included. By December, 1917, it had risen to 1,538,203 officers and men. Since December 31 the increase in the size of the Army has continued.

The mobilization of the National Guard, the concentration and the hurried recruiting of the Regular forces, the mobilization of the National Army, the great force of drafted men suddenly called from home life to new environments—all these conditions have required great expansion of the Medical Department, with the application of the total professional knowledge of the country to the vast and relatively new sanitary problems involved.

The mobilization of such a large number of men has required a large amount of work for the physical examinations. Making physical examinations on so great a scale was a new experience for most of the physicians engaged. There were not in this country enough medical men of proper training to do the work adequately. It was very often necessary for medical officers to examine many more men during a given period of time than could be done by them with the proper degree of care. This was a military necessity. It was necessary to assemble such a large number of men in a short space of time and to examine them promptly.

During the first few months the work of making the physical examinations at the camp was on a basis of emergency work. It was done by a hastily assembled and frequently changing personnel. The examinations were conducted in any sort of a building that could be spared from the pressing need of shelter for troops or of anticipated medical need.

Consequently, it must be recognized that it was impossible for the number of experienced men available under the conditions as they existed to make the examinations of the number of men required properly in the time allotted so as to exclude all diseases or detect all defects.

Consequently, many men were inducted into the military service with diseases or defects undetected and unnoted. Hence the opinion that has frequently been advanced that because a man has been passed by his local board, advisory board, and the board at the mobilization camp, he was of necessity physically sound when he entered the military service is open to very serious criticism.

The work at the various camps and military posts in preventive medicine and the medical care of the sick or injured has required a large amount of work.

The following tabulation shows the expansion in brief of the Medical Department:

	June 30, 1917.	June 30, 1918.
Medical Corps, including Medical Reserve Corps	4,125	23,274
Dental Corps, including Dental Reserve Corps	86	2,977
Veterinary Corps, commissioned officers	57	1,539
Sanitary Corps	....	1,159
Army Nurse Corps	1,176	12,186
Enlisted Medical Department, all branches	16,773	153,295

A large number of hospital buildings in this country and abroad have been built, organized, and equipped. The bed capacity in hospitals in the United States available at the present time is 73,066. In addition to this number, 16,799 additional bed capacity is now under construction.

Reports of the various divisions of the Surgeon General's Office are to be found in the body of the report. In addition to the reports of the various divisions is a short report of the American Red Cross. While the American Red Cross, as it is needless to say, is not attached to the Surgeon General's Office, still, so much assistance has been rendered by this organization that a short summary of its work in connection with the Medical Department was thought desirable.

The necessity of military secrecy renders it advisable to include only a brief discussion of the work of the Medical Department with the American Expeditionary Force.

In the report of the Division of Sanitation will be found a brief discussion of some of the infectious diseases with a limited statistical discussion of the health of the Army for the first few months of 1918.

Speaking now of the calendar year 1917, the health of the Army was satisfactory. Had it not been for the extensive epidemics of infectious diseases which occurred in the camps throughout the country, and especially in the southern camps, and more especially among the southern troops in the southern camps, the figures would have been very satisfactory.

Many of the camps have been visited by epidemics of these diseases more or less peculiar to great aggregations of men. During the period a large number of men was assembled in our camps and held for extensive training, and some were sent overseas. These men came from every section of the great country, from every class, without reference to previous social status, educational qualifications, or personal habits. They came from infected and uninfected localities. Immunes, susceptibles, infected, have been brought together in the close contact that is a necessity in every military organization. To accomplish this great task without more or less spread of infection was an impossibility. Fortunately, advances in general sanitation, in water purification, in garbage and sewage disposal, in protective measures against typhoid fever by vaccinations, have largely eliminated from armies the intestinal diseases.

If the morbidity from typhoid fever had been as great in the Army during the year 1917 as during the Spanish-American War for each 1,000,000 men there would have been 140,000 cases and 1,400 deaths. Actually, the mean annual strength of the Army was 678,579. Thus there would have been expected 136,000 cases and 13,600 deaths. As it was, there were 297 cases and 23 deaths. The insanitary conditions seen at Camp Alger, at Jacksonville and Chickamauga in 1898 do not exist in the country to-day.

It was seen long before the assembly of troops had been begun that the acute respiratory diseases would be the greatest factors in morbidity and mortality. With this in view this office insisted that at least 45 feet of floor space and 500 cubic feet of air space should be allowed each soldier. It was necessary, however, for military reasons, these reasons being, namely, the urgent necessity of assembling, organizing, and equipping as large a force as possible of men in the given period of time, to overcrowd the facilities of the camps. Many of the deaths from the diseases to be discussed could, no doubt, have been prevented if the country and the department had been willing to purchase that advantage by delaying the calling and training of the soldiers until thoroughly satisfactory arrangements for clothing, housing, and caring for them had been matured. But such an advantage would have been dearly purchased if it had protracted the war or diminished the chance of a successful outcome. It is necessary to realize that to diminish the great loss upon the field of battle which would result from the delayed organization of the military forces of this country we must be prepared to accept a certain increased loss from deaths from infectious diseases that occur as a result of overcrowding the camps in this country.

Pneumonia, whether primary or secondary, caused approximately 65 per cent of the deaths from all causes in the United States. A large number of these deaths from pneumonias have been charged to measles, with which disease these pneumonias were complications. This places measles at the head of the list of the causes of deaths from disease in the United States for the year 1917. The international rule for the classification of deaths has been followed.

A large proportion of the infectious diseases, especially the pneumonias and measles, occurred in southern camps among southern troops. We find that the same conditions existed during the Civil War. While the northern troops suffered from epidemics of both pneumonias and measles the morbidity and mortality of these diseases was much more extensive among the southern troops.

The general admission rate for diseases for enlisted men serving in the United States for the year 1917 showed an increase over the corresponding rate for 1916. The rate in 1917 was 886.81, being an increase of 270.70 over the year 1916.

The death rate in 1917 also showed an increase over the corresponding rate for 1916 for diseases for enlisted men in the United States. In 1917 the rate was 5.34, which is an increase of 2.56 over that for 1916. An examination of the tables in the body of the report shows that for the special infectious diseases, namely, broncho-pneumonia, lobar pneumonia, measles, and cerebrospinal meningitis, the death rate for 1917 was 3.93. The corresponding death rate for these diseases in 1916 was 0.72. The increase, consequently, for the year 1917 over the year 1916 for these diseases was 3.21 per 1,000. Had this great increase not occurred in 1917, the death rate for diseases would have actually been less in 1917 than in 1916. Excluding these diseases the figures would then have been 1.41 for 1917 and 2.08 for 1916 per 1,000. It is shown also by an examination of the tables that in camps the death rate for the diseases mentioned was 5.59 per 1,000, while the corresponding rate for posts other than the large camps was 2.50. Thus, the death rate in the camps for these special infectious diseases was more than twice as high as for posts other than the camps.

In the same way as the death rate was increased in the camps so in a like manner though not in a corresponding degree the admission rate was increased.

The discharge rate for disability for enlisted men serving in the United States was considerably increased in 1917 over the corresponding rate for 1916. The chief surgeon, Western Department, remarks: "The hasty and superficial examinations given by inexperienced and indifferent medical examiners to applicants for enlistment, immediately following the declaration of war, is reflected in the enormous increase in discharges for disability existing prior to enlistment."

It was the opinion of the medical officers who signed the certificate of discharge for disability of the 15,882 such recommendations in the United States during 1917, that 14,774 were not in line of duty, and only 1,108 were in line of duty.

The noneffective rate for diseases, that is, the number of men absent each day from duty on account of diseases per 1,000 in the United States for 1917, showed a decrease from the year 1916, the rate in 1917 being 22.21 as compared with 26.30 in 1916.

For the American Expeditionary Forces the health conditions were entirely satisfactory. Since there was comparatively little fighting there were only a few deaths as a result of battle injuries.

In the tropical countries where American troops were serving the health rates were all satisfactory.

B. HEALTH OF THE ARMY.

A Comparative Study, 1820–1917.

The word health, like the word life, is almost indefinable. If ife be, as it has been said to be, the sum or resultant of the forces esisting death, health might be defined as the sum or resultant of he forces resisting sickness. The human individual passes through life cycle at some early stage of which normally the tide of life runs igh and health is at a maximum and at the end of which health anishes and death comes. We might conceive the period between hese limits as divided into grades from a maximum of 100 down to ero. But no method of measuring these grades in the individual or he group has been discovered or is in sight. In other words, we have o direct means of measuring health, individual or communal, and re compelled, therefore, to rely upon indirect or roundabout methods.

In a civilian population the usual or standard indirect method of neasuring community health is by the death rate or the proportion f deaths to the average population in a given period like a year. But n army differs in important respects from a normal civilian population. It is a selected group, admission to which depends upon the esult of a careful medical examination and withdrawal from which ccurs sometimes by death and sometimes by discharge. A common eason for the discharge is impaired health. The death rate in the rmy must be considered with constant reference to both of these cts. To get a true rate it would be needful to follow the lives of ersons discharged from the Army and include all deaths among hem occurring after discharge as a result of health impaired during he period of service. Under existing conditions this can not be one. On the other hand, Army men are supervised so closely that t is possible among them, as it is not among civilians, to get other ndirect measures of health than the death rate. We can determine he grade or stage of impaired health at which a man is laid off duty nd admitted to sick report in quarters or hospital, and get the number of men admitted to sick report each month or year. We can get lso the number of men discharged from the Army because of disability resulting from disease and the number of men each day who re sick in quarters or hospital. The strength of a post or command r the day is reported by the adjutant as the sum of those present nd those absent from duty. From these daily reports of strength e mean strength for the month or the year is derived. By comparing the returns of deaths or sickness with those of mean strength we n get the proportion of the former to the latter in four forms—the roportion of deaths, the proportion of men admitted to sick report, e proportion discharged from the Army because of disability, and e proportion constantly sick in quarters or hospital.

Thus our means of measuring the health of the Army are much ller and more satisfactory than our means of measuring the health f the civilian population. The most important means are (1) the eath rate; (2) the rate of admissions to sick report; (3) the rate of ischarge from the Army because of disability; (4) the noneffective rate. Subsidiary ways of measuring or investigating the health of the Army are by analyzing the death rate, admission rate, and case fatality rate of the more troublesome diseases and causes of death. In using any of these methods a comparison between Army figures for one time or place and those for another time or place is probably safer and more illuminating than a comparison between Army figures and those for any civilian population. To make the comparison in both forms, however, is better than to rely exclusively on either.

In military statistics it is customary to divide the Army into two groups, the commissioned officers and the enlisted men and noncommissioned officers, and to restrict ordinary health statistics to the latter class. This procedure has been indorsed by international commissions and will be followed in the present report. Unless otherwise stated the figures for the Army will be understood to apply only to the group of enlisted men and noncommissioned officers, but to embrace all branches of the Army, including Porto Ricans and Philippine Scouts.

Whether in a civilian population the death rate is or is not a significant index of community health depends upon the question whether the ratio between the number of deaths and the amount of sickness in the population changes little or much from one year to another and varies little or much in different communities or other classes under examination. It is customary to assume that this ratio changes little from time to time or place to place. The assumption has sometimes been put as follows: On the average, to every death in the general population there are about two years of sickness, including the cases ending in recovery along with those ending in death. The evidence in support of this assumption is meager and inconclusive largely because of the difficulty in defining and measuring the amount of sickness in the general population. Under the careful supervision to which soldiers are subject these difficulties are reduced to a minimum and it becomes far easier in the Army than in the general population, to measure the ratio between sickness and death and to determine whether that ratio remains approximately the same from year to year either at two years of sickness to each death or at any other figure. To answer the question it is well to disregard on one side admissions to sick report due to accidents or injuries and on the other side deaths due to such causes and to limit its comparison to one between the amount of sickness proper and the number of deaths from disease. That has been done in the following table for the 10 years of peace, 1907–1916, and for the anomalous year 1917 to which the present report relates.

TABLE NO. 1.—*Years of sickness, deaths from sickness, and years of sickness to each death in the United States Army (American troops) annually, 1907–1917.*

Year.	Years of sickness.	Deaths from sickness.	Years of sickness to one death.
1907	2,131	189	11.3
1908	2,371	235	10.1
1909	2,647	228	11.6
1910	2,183	175	12.5
1911	2,054	194	10.6
1912	1,991	189	10.5
1913	1,617	210	7.7
1914	1,720	208	8.3
1915	1,993	246	8.1
1916	2,322	258	9.0
Average	2,103	213	9.9
1917	14,359	3,257	4.4

Table 1, shows that on the average in time of peace there were about 10 years of sickness in hospital or quarters to each death and that the range during the decade was between 7.7 and 12.5 years. There is little evidence here to support the theory that sickness and death in the Army stand in a constant ratio to each other. It does show, however, that the ratio of sickness to death in the Army is much larger than in civil life. For this two reasons may be suggested. Many disabled soldiers are discharged for disability and when they die the deaths do not appear on that side of the ratio. Many soldiers are invalided in hospital or quarters who if in civil life and drawing wages would keep at work under like conditions. Thus the differences between soldiers and a normal group of civilians tend in time of peace to bring down the number of deaths among soldiers and to bring up the amount of reported disease among them. The unusual figures in 1917 show that the number of deaths in that year increased much faster than the amount of sickness, probably because many of the deaths were preceded by an unusually short period of reported sickness.

I. THE HEALTH OF THE ARMY NOW AND FORMERLY.

1. DEATH RATES SINCE 1820.

The death records of the American Army began in 1819, an earlier date than the beginning of the death records of any other army except the British, which go back to 1816, an earlier date also than the beginning of the death records of any American State. From that date the death records of the Army in time of peace make an almost unbroken series, the only missing years being 1833, 1834 and 1836, but the death records for the period of the Mexican War and the Civil War are also lacking or incomplete so that it was not until the Spanish-American War, at the end of the last century, that the Army's death records in time of war became trustworthy.

The following table and diagram show the general trend of change in the Army death rates since 1819.

TABLE No. 2.—*Death rate in United States Army (American troops) per 1,000, mean strength by decennial periods 1820–1909 and single years 1910–1917.*

Decade.	Decennial death rate.	Year.	Annual death rate.
1820–1829	33.6	1910	4.5
830–1839[1]	22.9	1911	4.8
840–1849[2]	20.9	1912	4.8
850–1859	25.2	1913	4.9
860–1869[3]	23.4	1914	4.5
870–1879	15.3	1915	4.6
880–1889	9.4	1916	5.2
890–1899	9.9	1917	6.8
900–1909	7.7	1910–1917 (average)	4.9

[1] Returns for 1833, 1834, 1836 not obtainable.
[2] Returns for 1847, 1848 (period of Mexican War) omitted as not reliable.
[3] Returns for 1862–66 inclusive (period of Civil War) omitted as not reliable.

Table 2 and Chart 1 show that the Army death rate in time of peace was highest in the first decade, 33.6 per 1,000, and lowest in the last eight years, 4.9 per 1,000, or about one-seventh of what it was 90 years before, and that in the intervening period the decrease was almost unbroken. In the early decades of the last century belonging to the Army even in time of peace was a highly dangerous occupation. This reduction of the death rate by six-sevenths reflects and to some degree measures the progress made in 90 years in protecting the health of men closely crowded together under Army conditions.

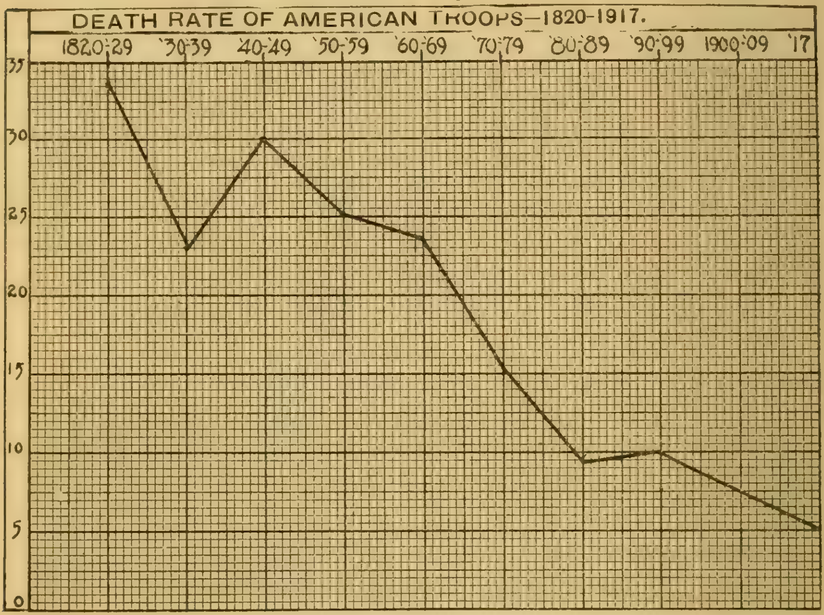

Chart No. 1.

It would be interesting to compare this decrease in the death rate in the American Army with the decrease during the same period in the death rate of the population of the United States or of any American States, but unfortunately comparable civilian records for the whole period do not exist. The best comparison would be with the male population of the age of enlisted men. The average age of enlisted men in the Army before its recent expansion was about 26.7 years. For a group of male civilians with which to compare them we must choose between those 20 to 29 years of age and those 20 to 34 years of age. The average age of the former in the United States in 1910 was 24.9 years and of the latter 27.1 years. Hence the best civilian age group to select is males, 20 to 34 years of age. But we do not know the death rate of this group in the United States as a whole for any date or in any large and representative part of the United States for any date before 1900. The best group to use for recent years is the males, 20 to 34 years of age, in the registration States of 1900. The death rate of this group was 7.8 per 1,000 in 1900, while the Army death rate in that year was 16.6 per 1,000, more than twice as great, an excess due mainly to the after effects of the Spanish-American War and to the disorders in the Philippines.

But the death rate of the civilian group in 1910 was 6.4 and of the Army 4.5 per 1,000, the latter being about seven-tenths of the civilian rate.

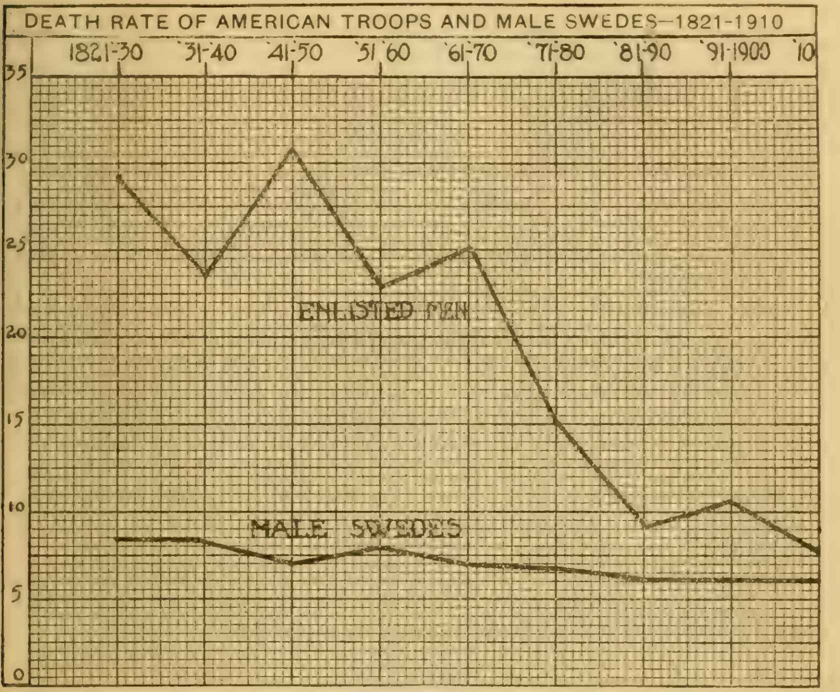

CHART No. 2.

The dearth of American civilian death rates for decades before 1900 can be met by recourse to the figures for males in Sweden, a country which has often been used as a standard. But in doing this we have to choose between two groups of males, those 15 to 34 years of age and those 25 to 34 years of age, for in the source at hand they are the only ones given. Naturally the former group has been preferred. The following table and diagram (Table 3, Chart 2) show the death rates of males 15 to 34 years of age in Sweden and of the American Army at various dates and the ratios of the latter to the former.

TABLE No. 3.—*Death rate United States Army (American troops) per 1,000 mean strength compared with death rate of Swedes, 1821–1910.*

Period.	Death rate of male Swedes 15 to 34 years of age.	Death rate in United States Army (American troops).	Ratio of Army death rate to that of Swedes = 100.	Period.	Death rate of male Swedes 15 to 34 years of age.	Death rate in United States Army (American troops).	Ratio of Army death rate to that of Swedes = 100.
1821-1830	8.5	29.1	343	1871-1880	6.7	15.1	227
1831-1840	8.4	23.5	281	1881-1890	6.1	9.1	150
1841-1850	7.2	30.8	429	1891-1900	6.0	10.7	168
1851-1860	7.9	22.9	291	1901-1910	6.1[1]	7.9	130
1861-1870	6.9	25.1	366				

[1] Estimated because the Swedish figures from the census of 1910 are not at hand.

From the beginning of the United States Army's death records to the end of the nineteenth century its death rates were greater than those of the males 15 to 34 years of age in the extremely healthy Swedish population at the same date. The death rate in each population group sank with little interruption during these 80 years, but that in the Army much faster than that in Sweden. As a result in the early decades the Army death rate was more than three times that of the Swedish group, at the end of the century the difference was less than half as great, and for the seven years 1911–1917 the American Army death rate (see Table 2) was less than that of males 15 to 34 years of age in Sweden for any period of which we have record. Apparently the death rate of the American Army now in time of peace is about the same as that of male Swedes 15 to 34 years of age, and less than that of males 20 to 34 years of age living in the registration States.

Table 2 (American troops only) also gives a clue to the number of deaths in 1917 which can fairly be ascribed to the abnormal conditions of that year. The lowest recorded death rate in the Army, including officers and enlisted men and Porto Ricans and Philippine Scouts as well as American troops, was 4.39 per 1,000 in 1910. If this death rate be applied to 678,579, the mean strength of the Army in 1917, it indicates that 2,979 deaths would have occurred had the minimum death rate prevailed. The difference between this computed number and the number of deaths which actually occurred is 1,180, and this is apparently an approximate measure of the number of deaths in 1917 above the normal and so of the loss of life attributable to the unfavorable conditions resulting from the sudden and enormous expansion of the Army between March, 1917, and January, 1918.

2. RATES OF ADMISSION TO SICK REPORT SINCE 1820.

When anyone in the Army is physically unable to report for duty he is enrolled as sick. The decision whether he is or is not sick is made in the first instance and ordinarily by himself in applying for exemption from duty. It is then reviewed by the medical officer, who may decide that he is able to do duty but who probably in most cases accepts the man's judgment. If the man is adjudged sick, he may be allowed to remain in quarters or he may be sent to the hospital. Which course is taken depends upon many considerations. Probably the line between those who are and those who are not admitted to sick report is drawn at various posts and in successive years with greater uniformity than the line between those who are admitted to hospital and those who are treated in quarters. For this reason the number and proportion of those admitted to sick report is a safer index of health than the number and proportion of those admitted to hospital. The unit in this tabulation is the admission not the person admitted, a fact which explains why the rate so often runs above 100 per cent.

Persons admitted to sick report fall into two main classes, those whose condition is due to external agents, producing accidents or wounds, for which the medical and sanitary authorities of the Army ordinarily have no responsibility, and those suffering from various diseases. The proportion of admissions to sick report for disease is probably a better index of health conditions than the proportion of admissions to sick report for all causes, but in the early annual reports of the Surgeon General the distinction between these two classes was disregarded. The figures of Table 4, therefore, refer to admissions for all causes.

TABLE No. 4.—*Rate of admission to sick report in United States Army (American troops) per 1,000 mean strength by decennial periods, 1820-1909, and single years, 1910-1917.*

Decade.	Decennial rate of admission to sick report.	Year.	Annual rate of admission to sick report.
1820-1829	2,489	1910	950
1830-1839 [1]	2,585	1911	936
1840-1849 [2]	2,935	1912	824
1850-1859	2,853	1913	672
1860-1869 [3]	2,609	1914	666
1870-1879	1,838	1915	745
1880-1889	1,508	1916	748
1890-1899	1,429	1917	975
1900-1909	1,388	1910-1917 (average)	814

[1] Information for 1833, 1834, and 1836 not obtainable.

[2] Statistics during the period of the Mexican War, 1847 and 1848, not reliable.

[3] Statistics during the period of the Civil War, 1862-1866, not reliable.

Table 4 shows that the health of the Army measured by the proportion of sick has been steadily and rapidly improving since the middle of the nineteenth century and thus supports and confirms the conclusion already drawn from Table 1. The improvement measured by the proportion sick is less than the improvement measured by the death rate; the average rate of admission to sick report between 1910 and 1917, inclusive, being a little more than one-fourth of the maximum while the death rate in the same period was only one-seventh of the maximum. In another respect also the results of the two measurements differ; the highest death rate was in the twenties and the highest sickness rate in the forties of the nineteenth century. The most striking coincidence in the two tables is found in the steady and rapid decrease both of sickness and of death in the Army since the sixties, probably due to various sanitary improvements growing out of discoveries in the germ theory of disease.

3. RATES OF DISCHARGE BECAUSE OF DISABILITY SINCE 1820.

A soldier who has been certified by a medical officer to be permanently incapacitated for military service is examined by a board of medical officers and on the basis of its report is or is not discharged because of disability. In the older records of the War Department the distinction between disability due to disease and disability due to external causes was disregarded and for that reason in the following table all discharges for disability are included. But during the five years, 1912-1916, of all discharges for disability nearly nine-tenths were due to disease and only about one-tenth to external causes. So the changes in the total discharges shown by Table 4 would probably be much the same if the discharges due to external causes were excluded.

TABLE NO. 5.—*Rate of discharge for permanent disability in United States Army (American troops) per 1,000 mean strength by decennial periods, 1820–1909, and single years, 1910–1917.*

Decade.	Decennial rate of discharge.	Year.	Annual rate of discharge.
1820–1829	26.6	1910	14.0
1830–1839 [1]	29.4	1911	13.9
1840–1849 [2]	32.1	1912	13.4
1850–1859	23.1	1913	13.2
1860–1869 [3]	19.1	1914	13.0
1870–1879	31.0	1915	14.3
1880–1889	31.9	1916	16.5
1890–1899	15.5	1910–1916 (average)	14.0
1900–1909	22.3	1917	27.6

[1] Information for the four years 1833, 1834, 1836, and 1837 not obtainable.
[2] No reliable statistics for the Mexican War period, 1847 and 1848.
[3] No reliable statistics for the Civil War period, 1861–1866.

The discharges due to permanent disability remained until after 1890 at about a constant rate or certainly with no tendency to a steady decrease. Examination of the figures for single years[1] shows that the Spanish-American War was accompanied and followed through several years by a high discharge rate. The rates for 1895–1897 averaged below 10 and were the lowest on record; they were followed by a rate of 11.6 in 1898 and 27.4 in 1899; for eight years thereafter the rate did not fall below 20. It seems likely that many persons were then taken with the Army who under ordinary conditions in time of peace would have been rejected as below the physical standards and that a considerable proportion of them, after being accepted, could not meet the exacting demands of army life. The sharp increase in the proportion of men discharged for disability in 1917 when it was almost double what it had been on the average during the preceding seven years confirms this theory. Probably many men volunteered or were summoned for examination and were passed as physically sound by the various boards who would not have been accepted if the pressure to get men and the little time available for examining each man had not combined to lower the standard actually used by the examining authorities.

4. NONEFFECTIVE RATES SINCE 1870.

The noneffective rate means the average number of men off duty per 1,000 mean strength. It is found by dividing the total time in days within the year of the enlisted men who were off duty because of ill health by the number of days in the year to get the average number of persons off duty on any day and dividing this quotient by the mean strength to get the rate.

Noneffectiveness is of two kinds, one in which the cause is disease, another in which the cause is a wound or other injury. As the duty of the medical force centers about protection from disease, probably the noneffective rate due to disease would be the better form to use as a measure of the health of the Army, but because in earlier reports the two kinds of noneffectiveness were not invariably distinguished they have been treated together in this paragraph. The figures for noneffectives, unlike those previously reviewed, run back only to the years just after the close of the Civil War.

---

[1] Report of the Surgeon General, 1913, p. 25.

TABLE NO. 6.—*Noneffective rate in United States Army (American troops) per 1,000 mean strength by decennial periods, 1870–1909, and single years, 1910–1917.*

Decade.	Decennial noneffective rate.	Year.	Annual noneffective rate.
1870–1879	46.2	1910	35.9
1880–1889	43.4	1911	33.3
1890–1899	45.9	1912	30.1
1900–1909	52.8	1913	24.3
		1914	24.0
		1915	25.9
		1916	28.0
		1917	25.2
		1910–1917 (average)	28.3

Table 6 shows that there was no decrease but perhaps a slight increase in the noneffective rate between 1870 and 1910. An examination of the rates for single years [1] shows the maximum rate (828 per 1,000) was in 1898 and that it fell from that figure almost without interruption until 1914 when it was less than one-third of what it had been 16 years earlier and below the rate of any previous year.

We may state the results from this analysis of changes in the health of the Army in the following conclusions:

1. The death rate has been falling from the first and practically without interruption.
2. Sickness measured by the admissions to sick report has been falling since the forties.
3. Permanent disability leading to a discharge from the Army increased sharply at the time of the Spanish-American War.
4. Noneffectiveness leading to temporary exemption from active duty also increased sharply in the same period.
5. The former but not the latter increased notably in 1917 indicating that both of these forms of imperfect health become much more common in the Army in time of war.

All four methods of analysis concur in indicating that during the period between 1910 and the entrance of the United States into the present war the health of the Army was better than at any previous period.

5. MONTHLY VARIATIONS IN THE HEALTH OF THE ARMY IN 1917.

That the results reached by different methods of testing the health of the Army do not agree in detail but do have a general similarity has already been made clear. In dealing with more special problems it seems hardly worth while to use all of these methods and if that is not to be done a selection must be made. On the whole and for the purposes of this report the death rate seems to be the best single test of the Army's health. It is better understood by the public and the sources of error in this field seem less important than in the others. Holding this view the further study of health in the army will stress this method of measurement.

---

[1] Report of the Surgeon General, 1913, p. 20.

The calendar year 1917 was occupied mainly with preparations for the participation of the United States in the great war which had been forced upon her. The mean strength of the Army in January, 1917, was only 217,272 officers and men all branches included and in March just before the declaration of war it had fallen to 194,165 officers and men, decreasing thus by more than one-tenth in two months as a result mainly of the return of certain mobilized elements of the National Guard to civil life. But by December, 1917, it had risen to 1,538,203 officers and men. That is, in the nine months between March and December the size of the Army was multiplied about eight times.

The year was mainly a period of organization and training. In comparison with the size of the Army the amount of active service was slight and the casualties resulting directly from the war were few. Only one-twentieth of the deaths occurred in Europe and of this small fraction two-thirds were due to disease. The new men brought into the Army were young and had been recently subjected to medical examination and selection. These influences were favorable to a low sickness and death rate. But on the other hand, when large numbers, some of them carrying in their systems the seeds of disease, are taken out of their home life and crowded together in camps and cantonments with the rapidity and under the conditions which prevailed almost of necessity in the last part of 1917, it is hardly possible to prevent epidemics of contagious diseases or to keep the mortality from such diseases during the early months down to the level maintained either before or after the period of rapid expansion.

The health of the Army month by month in 1917 is measured in the following table by showing the death rate for each month of that year:

TABLE No. 7.—*Death rate in Army (officers and enlisted men, all stations* [1]*), by months.*

Month.	1915			1917		
	Mean strength.	Deaths by month of occurrence.	Annual death rate.	Mean strength.	Deaths by month of admission to sick report.	Annual death rate.

CHART No. 3.

resulted from diseases or traumatisms leading to admission to sick report in the month indicated even though death did not occur until some later month. Some cases of admission to sick report in 1917 resulted in deaths in 1918. As the deaths in the later year have not yet been tabulated, the deaths in it from 1917 admissions could not be added to the 1917 record. Hence the monthly rates in Table 7 at least for the closing months of 1917 are somewhat too low. For 1915 the deaths have been charged uniformly to the month in which the death occurred rather than to the month in which the case was admitted to sick report. The deaths charged to any month have been multiplied by the ratio between 365 and the number of days in the month to get what would have been the annual number of deaths, had the conditions of that month continued for a year.

The figures in the last column of Table 7 show that after March, when the Army began to increase rapidly in numbers, the death rate dropped for six months with only one slight break, but rose again between September and November and in the latter month was higher than at any time of the year except February. For the three months of August, September, and October, the rates were below those for the corresponding months of 1915, but for the other nine months and for the year as a whole the 1917 rates were somewhat higher. In view of the conditions with which the Army was struggling in 1917, the record as a whole is a gratifying witness to the efficiency of the measures taken to protect the health of the soldiers.

II. The Health of the Army Analyzed.

The connection between the health of the Army and geographical conditions is far more difficult to establish and measure than changes in the health of the Army from one year to another. The main reason is that many other differences affect health besides those dependent upon location and that they also, or many of them, vary with location. An example from racial statistics will illustrate my meaning. In 1916 the proportion of colored among the enlisted men in the Philippine Islands was 6 times as great and in Hawaii 16 times as great as in continental United States. As the death rate of the colored, in civil life at least, is higher than that of the white, no comparison between the mortality of troops in these three areas which failed to inquire into the differences in the racial elements would have much meaning for sanitary science. The best way to deal with this difficulty is probably to examine and if possible to eliminate the simpler or more obvious causes before investigating the more complex or elusive ones. Following this method we may first examine the influence of race upon army health and then return to the more difficult subject of geographical conditions.

1. THE HEALTH OF THE ARMY BY RACE.

Four racial strains are distinguished in the statistics of the American Army, the white, the colored, the Porto Ricans, and the Philippine Scouts. The table following shows the death rate of each of these groups during the decade 1908–1917.

CHART NO. 4.

TABLE No. 8.—*Death rate per 1,000 mean strength in United States Army (enlisted men), classified by race, for the decade, 1908–1917.*

Racial group.	Mean strength.	Average number of deaths annually.	Death rate.
White	130,660	711	5.44
Colored	5,577	50	9.02
Porto Ricans	770	3.4	4.42
Philippine Scouts	5,293	26	4.89

Table 8 shows that the death rate among colored enlisted men for the decade exceeded that among whites by about two-thirds, but that the death rate among Porto Ricans and Philippine Scouts was less than that among whites. What we know about the mortality of whites and colored in the population of the United States agrees in general with the preceding results, but it is certain that the mortality of the population of Porto Rico and the Philippines is greater than that of American whites. In 1915–1916 the death rate in Porto Rico was 22.0 per 1,000, that in the Philippine Islands in 1916 was 25.3, while that of the United States registration area was not far from 14 and that of the whole United States probably did not greatly exceed the same figure. We are put on inquiry, therefore, to find some reason for the lower mortality of Porto Ricans and Filipinos in the Army although the civilian death rate in those islands is much higher than in the United States. For Porto Rico the number of deaths, only 34, may be too small to yield a significant rate but for the Philippines no such explanation can apply. Are the Philippine Scouts subject to a more rigorous selection before admission or more readily discharged in case of disability?

The question deserves further examination which can be given by applying other health tests to these four racial groups. First, how do they compare in the ratio of admissions to sick report to mean strength? The following table answers the question.

TABLE No. 9.—*Admissions to sick report in United States Army (enlisted men), classified by race, for the decade, 1908–1917.*

Racial group.	Mean strength.	Admissions to sick report.	
		Average annual number.	Annual rate per 1,000.
White	130,660	118,378	904
Colored	5,577	5,299	949
Porto Ricans	770	742	967
Philippine Scouts	5,293	3,845	727

The figures in Table 9 strengthen the conjecture that the death rate of Porto Ricans in Table 8 rests on so narrow a basis as to be untrustworthy. In the present table sickness is shown to be a little more common among Porto Rican troops than among either white or colored. The sickness rate of the colored is greater than that of the whites but the difference in the amount of sickness is much less han the difference in the death rate of the two races. With reference o the Philippine Scouts the evidence supports that in Table 8 and ndicates that they are much freer from sickness than any one of he other three groups.

It is possible that the very low death rate and sickness rate of the ?hilippine Scouts are due to the fact that those whose health is im- paired either temporarily or permanently are discharged for dis- bility earlier and more regularly than soldiers, white or colored, inder similar conditions in the United States. To determine whether his is actually the case the following table has been prepared showing he rate of discharge of each of the four racial groups.

ABLE No. 10.—*Rate of discharge for permanent disability in United States Army (enlisted men), classified by race, for the decade 1908–1917.*

Racial group.	Mean strength.	Discharges for permanent disability.	
		Average annual number.	Annual rate.
Vhite	130,660	2,727	20.9
olored	5,577	118	21.2
orto Ricans	770	7	9.1
hilippine Scouts	5,293	47	8.9

The figures show that the rate at which both Porto Ricans and ?hilippine Scouts are discharged for permanent disability is less than ne-half as great as the rate at which whites and colored are dis- harged and thus give a negative answer to the hypothesis.

The Philippine Scouts, therefore, seem to have better health than merican troops, either white or colored. As the health of the popu- ation from which they are selected is certainly below that of Ameri- an whites and probably below that of American colored, we must uppose that these scouts are recruited by a more rigid and exacting elective process than that passed by American troops, either white r colored. Beyond this general conclusion the figures do not enable s to go.

2. THE HEALTH OF THE ARMY IN DIFFERENT PLACES.

A. UNITED STATES, HAWAII, AND THE PHILIPPINE ISLANDS.

Now that the racial statistics have been examined we are in a etter position to consider the effect of geographical location upon ealth. There are three main regions, the United States, Hawaii, nd the Philippines, in each of which soldiers belonging to the two nain American races, white and colored, have for years been sta- ioned in numbers large enough to furnish significant rates. The irst question to be raised, then, is this: What is the health of Ameri- an troops, either white or colored, in the United States, Hawaii, or he Philippines? Figures are available for each year since 1904. It s best to give the results for 1904–1916 together and those of 1917 eparately, because in the later year the abnormal conditions and he great size of the army would make an average including it far rom typical. For white troops the death rate, 1904–1916, was 5.08

in the United States, 3.03 in Hawaii, and 6.14 in the Philippines. For colored troops during the same period the death rate was 8.51 in the United States, 5.13 in Hawaii, and 7.56 in the Philippines. Seemingly for both races Hawaii is a more healthy location than the United States or the Philippines. The death rate of white soldiers is lower and of colored soldiers is higher in the United States than in the Philippines. In 1917 the death rate of white soldiers in the United States increased to 6.27 per 1,000 and of colored soldiers to 14.37 per 1,000, the unfavorable conditions of that year raising the white death rate about one-fourth and the colored death rate about two-thirds above its previous average. The changes in Hawaii were in the same direction and with a similar difference between the two races, but in the Philippine Islands the death rate of the soldiers of each race dropped off sharply. The figures then indicate that for each race Hawaii is a very healthy station and that while in all three regions the death rate of the colored soldiers is higher than that of the whites, in the United States it is higher by about two-thirds, and in the Philippine Islands by only one-fourth.

B. CONTINENTAL UNITED STATES.

The death rate has meaning only when it is based upon deaths enough to yield a significant average. The fact that in 1917 there were four States in which no death occurred in the Army, three in each of which there was only one death, and three in each of which there were only two, does not even suggest that these States or the soldiers stationed in them were remarkably healthy. The following table includes only those States in which at least 50 deaths occurred at Army posts in 1917. They are arranged in order of increasing death rate.

TABLE NO. 11.—*Death rate in Army (enlisted men), by location of command for States in each of which 50 or more deaths occurred, 1917.*

State.	Mean strength.	Deaths.	Death rate.	State.	Mean strength.	Deaths.	Death rate.
New York	52,942	108	2.04	Arizona	9,514	72	7.57
California	32,592	124	3.80	Georgia	39,653	317	7.99
Virginia	19,032	96	5.04	South Carolina	25,931	250	9.64
Kentucky	9,406	55	5.85	Missouri	5,003	52	10.39
Ohio	14,225	84	5.90	Kansas	15,836	235	14.84
New Mexico	13,902	93	6.69	Arkansas	10,763	211	19.59
Texas	89,861	641	7.13	Louisiana	5,829	132	22.65
Mississippi	9,522	67	7.04				

Table 11 does not clearly reveal any geographical grouping of the States with high or low Army death rates. It does show a large number of Southern States and only one-fifth of the northern on the list. But this may be due to the location of so large a number of camps in that part of the country. To determine whether the death rate of soldiers varied with the location of the camp the States have been combined into groups in the table following. In each group, it will be noticed, there were 50 deaths or more of soldiers and the rates, therefore are probably significant.

TABLE No. 12.—*Death rate in United States Army (enlisted men), by location of command for groups of States, 1917.*

Group.	Mean strength.	Deaths.	Death rate.	Per cent of rural population to total, 1910.
Southern North Atlantic (N. Y., N. J., Pa.)	85,985	166	1.93	29.0
New England (Me., N. H., Vt., Mass., R. I., Conn.)	27,949	57	2.04	16.7
Eastern North Central (Ohio, Ind., Ill., Mich., Wis.)	47,220	122	2.58	47.3
Pacific (Wash., Oreg., Cal.)	52,348	171	3.27	43.2
Northern South Atlantic (Del., Md., D. C., Va., W. Va.)	38,016	144	3.79	65.0
Eastern South Central (Ky., Tenn., Ala., Miss.)	38,795	154	3.97	81.3
Mountain (Mont., Wyo., Colo., N. Mex., Idaho)	22,467	128	5.70	64.6
Basin (Ariz., Utah, Nev.)	12,654	84	6.64	62.2
Southern South Atlantic (N. C., S. C., Ga., Fla.)	79,068	590	7.46	81.6
Western South Central (Ark., La., Okla., Tex.)	116,579	994	8.53	77.7
Western North Central (Minn., Iowa, Mo., N. Dak., S. Dak., Nebr., Kans.)	36,254	317	8.74	66.7
United States	557,335	2,927	5.2	53.7

The table shows that the lowest Army death rates were in States north of Mason and Dixon's Line and the Ohio River and east of the Mississippi and that the highest rates were in States between the Mississippi River and the Rocky Mountains. In determining this geographical grouping two causes may have been at work. First, as the last column of Table 12 indicates, States with a low soldier death rate are the States with a large proportion of urban population, and vice versa. Secondly, States with a low soldier death rate are the states with a well developed public-health service. These two influences are closely interdependent for the public-health work in general and especially in the United States has been more needed and is now better developed in urban or densely settled areas. But the way in which these two influences are supposed to work is quite different. If the density of population is the main cause the low death rate would result from the fact that among the new recruits from urban districts the proportion who have already been exposed to the germs of various contagious diseases and have thus gained an increased power of resistance would be much larger than the proportion among the new recruits from rural districts. On the other hand, if the development of public-health work is the main cause the low death rate would result from the fact that among the new recruits from such States the proportion having a knowledge of the elementary principles of hygiene and sanitation and able and willing to cooperate with and reenforce the efforts of the medical staff would be much greater. It seems likely that the two sorts of influences have cooperated in bringing about the striking result, but it is difficult to see how that theory can be brought to a test of the figures.

3. THE HEALTH OF THE ARMY CLASSIFIED BY AGE.

In the tabulations for the calendar year 1917 with which this report is mainly concerned, no classification of the troops by age has been attempted and none of significance could be made because we do not know the mean strength by age. But in the reports for each of the nine years, 1905–1913, the mean strength, the deaths, and the three classes of data about the sick were reported in age groups and the

results invite examination. The material for any one of those years was not extensive enough to measure the influence of the age of the soldiers upon their health. For example, to the simple question: At what age are soldiers most healthy? the series of tables indicates the following answer: As measured by death rate, the healthiest age was, in one year, 15 to 19, in a second, 20 to 24, in a third, 30 to 34, in a fourth, 35 to 39, and in the five other years, 25 to 29; as measured by the proportion admitted to sick report, the healthiest age was, in four years, 40 to 44, and in five years, 45 to 49; as measured by the proportion discharged for permanent disability, the healthiest age was, in two years, 40 to 44, in two years, 50 and over, and in five years, 45 to 49; as measured by the proportion constantly noneffective, the healthiest age was, in two years, 45 to 49, and in six years, 35 to 39.[1] Clearly this answer does not go far toward settling the question to which it is addressed. That the healthiest age measured by any of these tests really changed thus from one year to another is most improbable. More light is thrown upon the inquiry when the returns of each of these nine years are combined into one table. The results are as follows:

TABLE No. 13.—*Health of United States Army (American troops), classified by age, 1905–1913.*

Age.	Mean strength.	Admissions to sick report.	Deaths.	Discharged for disability.	Constantly noneffective.
Under 20	1,552	2,068	5	47	74
20–24	19,938	21,310	49	481	763
25–29	13,947	10,145	31	255	411
30–34	6,704	3,833	19	113	168
35–39	3,299	1,709	14	45	78
40–44	1,671	824	12	19	39
45–49	873	432	8	8	20
50 and over	379	252	6	6	13

Ratio per 1,000 mean strength.

Age.	Admissions to sick report.	Deaths.	Discharged for disability.	Constantly noneffective.
Under 20	1,332	3.35	30.1	48
20–24	1,069	2.47	24.1	24
25–29	727	2.22	18.3	29
30–34	572	2.88	16.8	25
35–39	518	4.18	13.6	24
40–44	493	7.11	11.2	23
45–49	495	9.29	9.6	23
50 and over	665	16.12	16.4	34

Table 13 shows that admissions to sick report in hospital or quarters are most common among the very young soldiers and decrease steadily and rapidly up to the age 40 to 44 when they were not much more than one-third as common as among soldiers under 20 years of age. After that time of life they increased, but soldiers even at ages over 50 were admitted to sick report only half as often as their

youngest comrades. As this is contrary to the conditions in civil life, where sickness increases steadily with years, some explanation is needed. Perhaps men who for years have been under army discipline acquire ability to care for themselves, and habits diminishing their risk of sickness, which together more than neutralize the tendency to an increase of invalidity with age. This conjecture finds some support in the rate of the constantly noneffective. This is at a maximum among soldiers less than 20 years of age, and at ages between 20 and 50 is almost constant at one-half the proportion among the youngsters. Apparently the normal tendency to an increase of sickness in advancing years is about balanced by some other influence which may be the increasing ability and willingness of the older soldiers to avoid sickness. The proportion discharged for disability, likewise, is at the highest among boys under 20 years of age and very low at ages 45 to 49. The death rate is the only measure of health which reaches a minimum at 25 to 29, and thereafter goes up steadily.

4. THE HEALTH OF THE ARMY CLASSIFIED BY LENGTH OF SERVICE.

There is obviously a close connection between length of service and age. Because of that fact and with the material classified only by each of the two characteristics separately, and not by the two in combination, it is almost impossible to distinguish between the influence of one factor and that of the other. What is needed is a large body of material classified both by age and by length of service. This would enable us to measure, for example, how the health of soldiers 20 to 24 years of age varies with the length of their service, or how the health of soldiers who have been in the Army between five and six years varies with their age.

The material in hand, speaking for the nine years 1905–1913, has been combined into a table like that just given for age.

TABLE NO. 14.—*Health of United States Army (American troops), classified by length of service, 1905–1913.*

Length of service.	Mean strength.	Admissions to sick report.	Deaths.	Discharged for disability.	Constantly noneffective.
Less than 1 year	11,458	15,362	39	486	533
1 to 2 years	8,319	6,684	13	147	287
2 to 3 years	7,635	5,877	13	81	210
3 to 4 years	4,071	2,705	8	58	112
4 to 5 years	3,255	2,036	7	43	83
5 to 9 years	7,986	5,080	25	103	215
10 years and over	5,639	2,829	38	55	127

Ratios per 1,000 mean strength.

Length of service.	Admissions to sick report.	Deaths.	Discharged for disability.	Constantly noneffective.
Less than 1 year	1,341	3.4	42.4	46.7
1 to 2 years	803	1.6	17.7	33.4
2 to 3 years	770	1.7	10.6	27.0
3 to 4 years	664	2.0	14.3	27.7
4 to 5 years	626	2.2	13.2	25.3
5 to 9 years	636	3.1	12.9	26.9
10 years and over	502	6.7	9.8	22.0

The preceding table shows that admissions to sick report among soldiers in their first year of service are very much more common than among men who have become accustomed to Army life, indeed, more than twice as common as among men who have been in the Army three years or longer. As the differences revealed by this table are more marked than those appearing in the preceding we have good grounds for concluding that the high sickness rate of soldiers under 20 is due not to their youth in years, but to their being raw recruits. The death rate column tells much the same story, a high rate among the recruits not equaled till the group of veterans or those who have been in the Army at least 10 years is reached. All the columns of both tables emphasize the fact that the first year of service is a time of probation in its literal sense, and that of those joining the colors not a few fall by the wayside before the first year of service is over.

5. HEALTH OF THE ARMY CLASSIFIED AS OFFICERS AND MEN.

The death rate of officers is in some years below and in others above that of enlisted men. Thus in 1915 the death rate of officers was about one-fifth less than that of the men, but in 1916 it was about one-half more. To get the general or prevailing difference the figures for the period 1905–1916 have been combined. These show a death rate of 4.89 per 1,000 for the officers and 5.08 for the men. The death rate of the men exceeds that of the officers by about 6 per cent. This slight difference is probably the resultant of counteracting tendencies. Officers by their greater knowledge and income are better able to protect their own health. The proportion of colored among the officers is less than that among the men and, as we have seen, the death rate of the colored is higher than that of the white. But, on the other hand, officers on the average, no doubt, are considerably older than the men and would naturally show the higher death rate characteristic of their age. Influences of the former class evidently overbalance slightly those of the latter.

The change in 1917 affected the two classes in opposite ways, the death rate of the officers dropping to 3.40, or about three-fourths of the previous average, while the death rate of the enlisted men rose to 6.32, an increase of about one-fourth. Obviously the unfavorable health conditions in the year 1917 pressed heavily on the men but not on the officers.

III. THE CAUSES OF DEATH.

1. GENERAL.

This is at once the most important and the most difficult branch of the statistical work of the Surgeon General's Office. It is difficult mainly because of the uncertainty surrounding the cause of death. When a soldier dies immediately of a bullet wound or other casualty, it is easy to assign the cause of death. But when the wound leads to a long illness during which various complications arise and at last result in death, it is often difficult to assign the main cause. The same statement applies with greater force to a death from a complication of diseases. Indeed, under such circumstances the very phrase "cause of death" is objectionable because it involves the questionable or erroneous assumption that there is a cause of death, whereas in truth nearly every death from disease is the result of a large number of interacting influences, and the selection of the main or primary cause is often a matter of difficulty on which physicians differ widely and which can be decided, if at all, only by an autopsy. In this field, therefore, the proportion of erroneous returns is much wider than in any other with which we have to deal and often wide enough to make the interpretation doubtful. It is usually safe, however, to assume that the errors in the returns do not change their significance materially from one year to another. If so, changes from year to year in the reports are trustworthy indices to changes in the conditions even when the margin of error in the figures of any and every year is probably a wide one.

The number of causes of death from disease which have been used on death certificates, military or civilian, runs up into the thousands. Many of them are merely alternative names for the same morbid condition and others are cloaks, more or less transparent, for professional ignorance. Under these conditions statisticians in various fields have long concerned themselves with the construction of the best practicable nomenclature and classification of causes of death. The first International Statistical Congress ever held, that of Brussels in 1853, gave attention to the subject, and in its successors the reports of committees and the discussions upon them have helped to clarify the situation. More recently international conferences devoted exclusively to this topic have been held at Paris, and but for the war the third would have been held in Washington in 1919. These various efforts toward uniformity have led gradually to the displacement of the several classifications, national, departmental or other, by the international classification now used by the United States Army as well as by the Federal Bureau of the Census and American registration offices without exception.

In Army statistics the most fundamental classification of causes of death is into diseases or internal causes and traumatisms or external causes. Even here, however, the accepted classification does not seem in all respects lucid and reasonable. Why, for example, should poisoning by food be classified as a traumatism and poisoning by drink, i. e., alcohol, as a disease? Yet, in general, the classification rests on a valid distinction and leads to significant results, and this is, perhaps, all that can be expected. The following table shows the death rate from each of these two classes of causes for a series of years.

TABLE No. 15.—*Death rate of United States Army (American troops) from disease and from external causes, 1907–1917.*

Year.	Mean strength.	Deaths from—		Death rate from—	
		Disease.	External causes.	Disease.	External causes.
1907	54.949	189	130	3.44	2.37
1908	67.515	235	179	3.48	2.65
1909	75,399	228	142	3.02	1.88
1910	71,814	175	145	2.44	2.02
1911	73.023	194	154	2.66	2.11
1912	79.613	189	192	2.37	2.41
1913	81,697	210	187	2.57	2.29
1914	88.133	208	184	2.36	2.09
1915	94.729	246	190	2.60	2.01
1916	105.720	258	258	2.60	2.60
Total	792,592	2,132	1.761	2.69	2.22
1917	639,645	3,257	779	5.09	1.22

As would be expected in time of peace, the death rate from disease during the decade 1908–1916 was higher as a rule that the death rate from external causes, varying between 2.36 and 3.48 per 1,000. But in 1917 it went up to 5.09, higher by nearly one-half (46 per cent) than in 1908, the highest of the preceding 10. Meantime the death rate from external causes, which in the preceding 10 years had varied between 1.88 and 2.65 per 1,000, fell to 1.22, less than two-thirds of the lowest rate in the preceding decade. Thus the high rate in 1917 as the resultant of an extremely low rate for external causes more than outweighed by a high rate for disease. Many of these deaths from disease, no doubt, could have been prevented if the country and the department had been willing to purchase that advantage by delaying the calling and training of the soldiers until thoroughly satisfactory arrangements for clothing, housing, and caring for them had been matured. But such an advantage would have been dearly purchased if it had protracted the war or diminished the chance of a successful outcome.

2. THE MOST IMPORTANT CAUSES OF DEATH.

In order to indicate the distribution of the leading diseases in 1916 and 1917 a table has been prepared showing each disease which in either year caused at least 1 per cent of the deaths from disease. They have been arranged in the order of their deadliness.

TABLE NO. 16.—*Number and per cent of deaths from the main diseases United States Army*[1] *(enlisted men), 1916–1917.*

Diseases.	Deaths.		Diseases.	Deaths.	
	Number.	Per cent.		Number.	Per cent.
1916.			1917.		
Tuberculosis (all forms)	39	14.2	Measles	975	29.9
Pneumonia	29	10.6	Lobar pneumonia	798	24.5
Organic heart disease	18	6.6	Epidemic cerebrospinal meningitis	332	10.2

All deaths from disease	274	100.0	All deaths from disease	3,257	100.0

---

[1] Including American and native troops.

The table shows that the doubling of the death rate from disease in 1917 was attended by a great reduction in the number of causes to each of which a significant proportion was attributed. In 1916 there were 22 causes and in 1917 only 8, each of which produced at least 1 per cent of all the deaths of the year. Of the 8 leading causes of death in 1917 there are 5 of an epidemic character of which measles is the most important.

To interpret aright the large number of deaths in 1917 ascribed to measles, it is needful to understand how deaths due to a complication of causes are treated under the international usage to which reference has already been made.

The International Commission on the Classification of Causes of Death at its last meeting held in Paris in 1909 appointed a special committee to consider the proper treatment of joint causes of death and recommended that the existing practice be continued until the committee should report. That practice is expressed by the following rules:

1. If one of the two diseases is an immediate and frequent complication of the other, the death should be classified under the head of the primary disease.
2. If the preceding rule is not applicable, the following should be used: If one of the diseases is surely fatal and the other is of less gravity, the former should be selected as the cause of death.
3. If neither of the above rules is applicable, then the following: If one of the diseases is epidemic and the other is not, choose the epidemic disease.
4. If none of the three preceding rules is applicable, the following may be used: If one of the diseases is much more frequently fatal than the other, then it should be selected as the cause of death.
5. If none of the four preceding rules applies, then the following: If one of the diseases is of rapid development and the other is of slow development, the disease of rapid development should be taken.
6. If none of the above five rules applies, then the diagnosis should be selected that best characterizes the case.

C. MOBILIZATION OF THE ARMY.

The conditions presented by the Army for 1917 are so completely novel that the routine report of former years becomes quite inadequate for this. From a strength of 217,272 in January, 1917, the Army increased to 1,538,203 in December, 1917. This increase occurred, moreover, not uniformly, but, on the contrary, was largely confined to the last six months of the year, during five of which the monthly increments exceeded the size of the Regular Army in the preceding December (Chart 9). Indeed, in the single month of September the increment to the Army was about four times the strength of the Regular Army in December, 1916. The mobilization during September of 462,000 men and the preparations for that mobilization were a severe strain on all branches of the War Department, and it was well nigh inevitable that they should have affected unfavorably the record that the Medical Department made in the nine months following July 1, 1917.

The Army of January, 1917, included about 115,000 officers and men of the Regular Army who were continued from December, 1916. During the first six months the strength of the Regular Army rose to 245,000, indicating that there had been a net gain by enlistment of about 130,000 recruits, so that on June 30 about half of the Regular Army consisted of men who had recently left civil life. On June 30, 1917, there were also about 111,000 men and officers in the National Guard (A. G. Rept. 1917, p. 45). These, more or less commingled with the National Army, were located in southern camps. The names of these camps with maximum strength and months thereof are:

Camp.	Location.	Maximum strength, 1917.	Month.	States from which troops came.
Beauregard	Alexandria, La.		December	Arkansas, Louisiana, Mississippi.
Bowie	Fort Worth, Tex.	26,901	October	Oklahoma, Texas.
Cody	Deming, N. Mex.	29,945	December	Minnesota, Iowa, Nebraska, South Dakota, in part.
Doniphan	Fort Sill, Okla	27,862	October	Kansas, Missouri.
Greene	Charlotte, N. C.	39,054	November	Idaho,[1] Montana, North Dakota, Oregon, South Dakota, in part, Washington, Wyoming.
Hancock	Augusta, Ga	28,426	do	Pennsylvania.
Kearney	San Diego, Cal	24,132	do	Arizona, California, Colorado, New Mexico, Utah.
Logan	Houston, Tex	33,346	December	Illinois.
McArthur	Waco, Tex	27,294	October	Michigan, Wisconsin.
McClellan	Anniston, Ala.	35,016	September	Delaware, District of Columbia, in part, Maryland, New Jersey, Virginia, in part.
Sevier	Greenville, S. C	27,302	December	District of Columbia, in part; North Carolina, South Carolina, Tennessee.
Shelby	Hattiesburg, Miss			Indiana, West Virginia, Kentucky.
Sheridan	Montgomery, Ala		October	Ohio.
Wadsworth	Spartanburg, N.C.	31,007	November	New York.
Wheeler	Augusta, Ga	25,168	do	Alabama, Florida, Georgia, Virginia, in part.

[1] This camp was occupied by these troops for a part only of the last four months of the year.

The details of weekly changes in the strength of these camps are given in Charts 10–39.

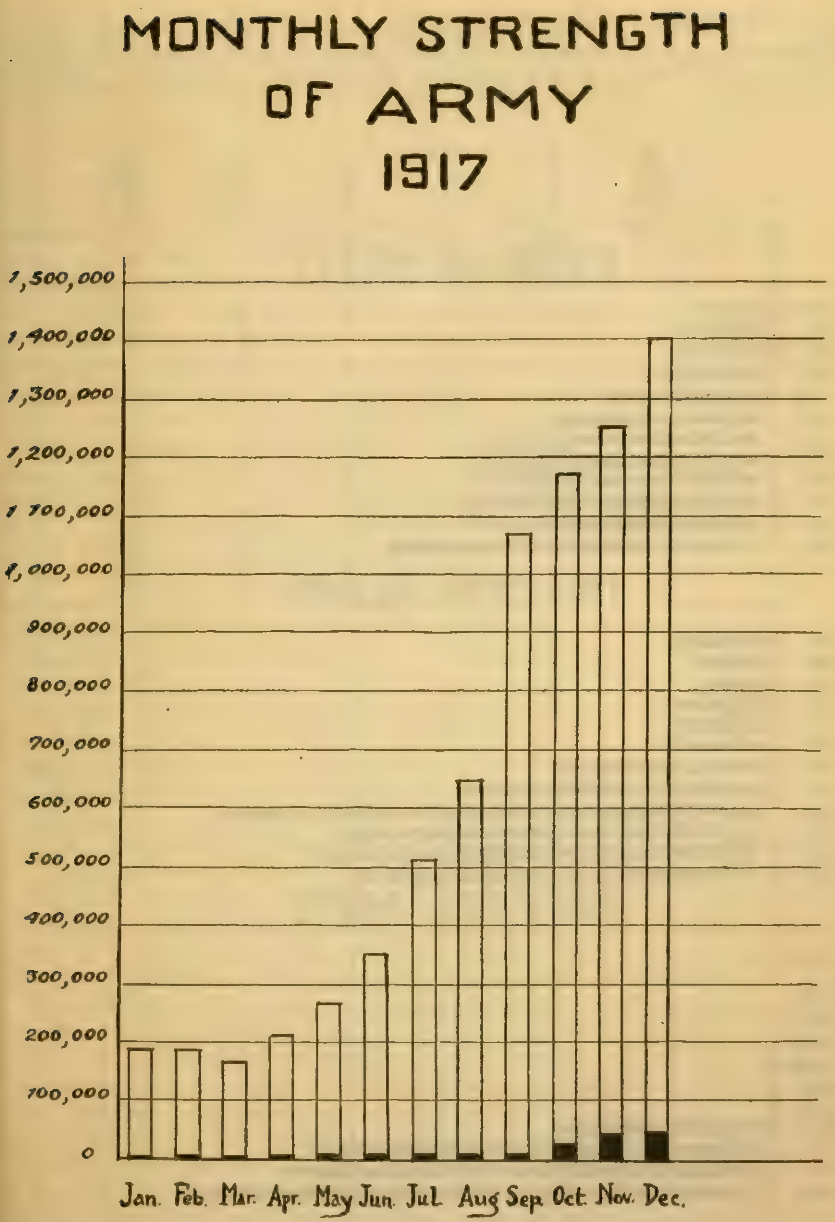

CHART NO. 7.

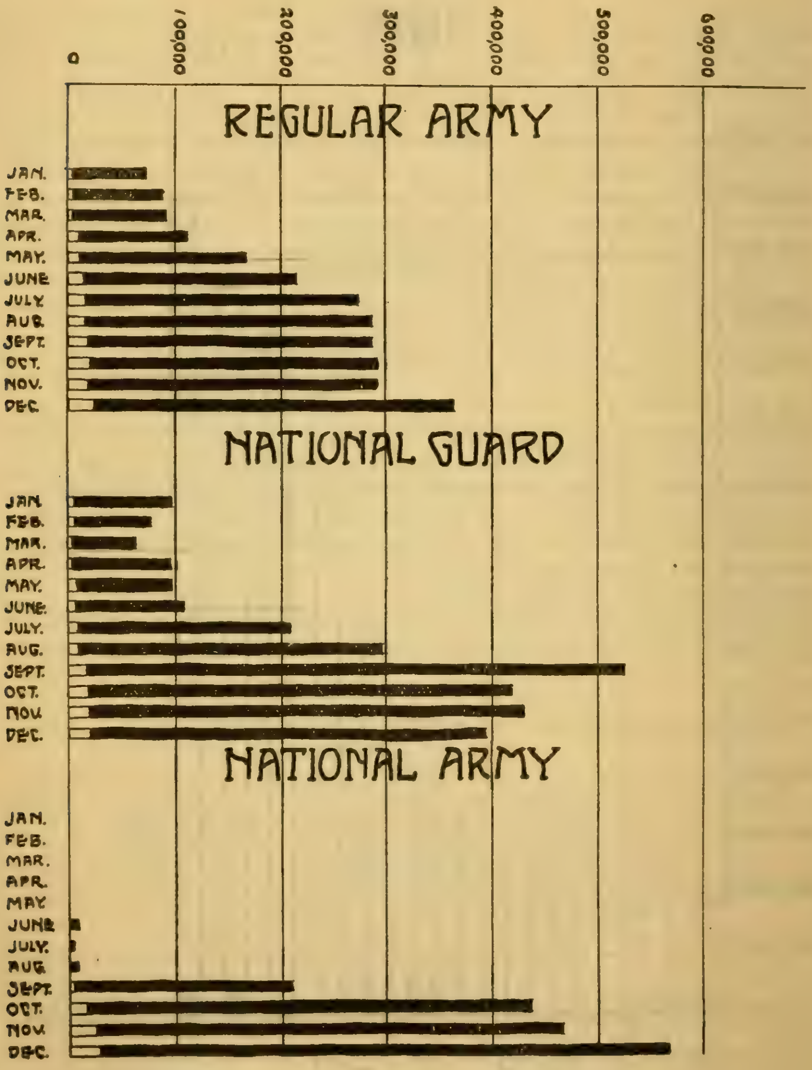
Enlisted men, American troops. The highest column gives the number of white troops, the black column of colored troops.

In September, 1917, the entrainment of the first call for the first draft was made. This comprised 5 per cent of the 687,000 men of the first draft, or about 34,000 white men. The second call was for about 275,000 white men. The third call was for about 126,800 men. Of these about 9,300 men were colored, sent to Camps Pike, Gordon, and Jackson. The fourth call of October 13, comprised about 47,000 men, of whom 29,000 were colored. Subsequent calls in November and December yielded about 36,000 additional men. The details of these distributions to the various camps are given in Charts 10–25.



STRENGTH BY MONTHS.

CHART No. 8.

I. THE PHYSICAL EXAMINATIONS AT LOCAL AND MEDICAL ADVISORY BOARDS.

The physical examination at local draft boards lay entirely under the jurisdiction of the Provost Marshal General who has already published an account of its method and results. (Rept. P. M. G.

to the Sec. of War, 1918.) But since the Medical Department of the Army had to deal with those who were accepted by the local and medical advisory boards as physically fit, it is desirable here to consider the Provost Marshal General's conclusions:

First, it appeared that of 2,510,706 examined physically by the local boards 29.1 per cent were rejected as physically unfit and 70.8 per cent were accepted as fit. In general, States between the Mississippi River and the Sierra Nevada Mountains had a low rate of rejections, 14 to 26 per cent (except Nevada, which had 30 per cent). The States of the Northeast had relatively high rates of rejection varying from 47 per cent for Pennsylvania to 30 per cent for New York. The high rejection may be due to careful selection and high ideals on the part of the examiners; in part it may be due to a physical inferiority of the men examined. The Provost Marshal General remarks (p. 46), "doubtless the local boards varied extremely in the strictness of their examinations."

The machinery of selecting the first contingent of the National Army was assembled with swiftness. The selective service act was passed on May 18, and "Regulations governing physical examinations," were issued July 2 (Form No. 11, P. M. G. O.). Beginning about July 20, local boards made examinations under these regulations. The regulations were brief (about four pages) and were replaced in August by "Instructions for the Physical Examination of Drafted Men at National Army Cantonments," issued by the Surgeon General and on December 15, by "Selective Service Regulations," including "Directions for physical examination," about seven pages in extent. Under the system which prevailed during the greater part of the time of selecting the National Army, covered by this report, "there was no appeal from local board ruling on physical qualification." The later regulations provided for sending doubtful cases to a medical advisory board. The accepted men were ordered to entrain on certain days to go to the prescribed camps. On each train they were accompanied by one of their number in charge of the party. Arriving at camp the physical examination took place, usually the next day, sometimes on the same day, sometimes after several days' delay. The physical examination took place in some available building, usually in a barrack or infirmary.

The problem of examining physically from 1,000 to 3,000 men in one day was a novel one and was met in various ways at different camps by the division surgeon. He usually appointed a chief medical examiner under whose direction stations were provided for the different examiners and barriers were created and orderlies posted to secure the regular movement of the recruits.

Different types of physical examination were developed at different camps. In one type there were routine examiners for the main examination line and for doubtful cases a board of specialists in another part of the building. In another type the specialists were stationed alongside of the routine examiners and observed doubtful cases there.

CHART No. 9.

On a different basis the examinations may again be classified into two types. In some camps there is only a single team of examiners who are all engaged in examining the one line. This type is characterized by great thoroughness and speed in completing the survey of the individual man. In another type there are two, three, or even six teams, each team consisting naturally of fewer officers than in the first type since the number of medical officers available for the work is about the same in different camps. A careful comparison of the two methods shows that the number of recruits examined per examination officer is approximately the same. In any case, the examination at the mobilization camp is in general a more thorough one than that received from the local board.

The results of the physical examination at the mobilization camp are recorded on Form 1010 P. M. G. O., and in most camps also in greater detail in the Special Medical Form No. 88. The latter form, being on a 5 by 8 card, is filed and retained as a permanent record at most of the camps.

The proportion of rejections at each of the National Army camps is shown in the following table, taken from the report of the Provost Marshal General to the Secretary of War on the first draft under the Selective Service Act of 1917 (p. 46).

TABLE NO. 17.—*Rejections, physical examinations at camps.*

Specific camp showings for physical rejections.	States contributing to camp.	Number arrived.	Number rejected.	Per cent of arrived.
Camp Custer	Michigan and Wisconsin	17,487	1,660	9.49
Camp Devens	Connecticut, Maine, Massachusetts, New Hampshire, New York, Rhode Island, and Vermont.	36,082	4,281	11.87
Camp Dix	Delaware, New Jersey, and New York	19,804	1,573	7.94
Camp Dodge	Illinois, Iowa, Minnesota, and North Dakota	20,505	690	3.36
Camp Gordon	Alabama, Georgia, and Tennessee	19,935	1,556	7.80
Camp Grant	Illinois and Wisconsin	26,658	1,148	4.30
Camp Jackson	Florida, North Carolina, and South Carolina	17,754	1,975	11.12
Camp Lee	Pennsylvania, Virginia, and West Virginia	36,938	920	2.49
Camp Lewis	California, Idaho, Montana, Nevada, Oregon, Utah, Washington, and Wyoming.	46,313	5,095	11.00
Camp Meade	District of Columbia, Maryland, Pennsylvania, and Tennessee.	35,971	2,245	6.24
Camp Pike	Alabama, Arkansas, Louisiana, and Mississippi	24,389	1,819	7.46
Camp Riley	Arizona, Colorado, Kansas, Missouri, Nebraska, New Mexico, and South Dakota.	38,975	281	.72
Camp Sherman	Ohio and Pennsylvania	9,850	1,012	10.27
Camp Taylor	Illinois, Indiana, and Kentucky	27,903	2,143	7.68
Camp Travis	Oklahoma and Texas	32,746	993	3.03
Camp Upton	New York	31,423	2,318	7.38
Total		442,733	29,709	

II. MOBILIZATION CAMPS.

The General Staff of the Army early decided upon 16 cantonments for the new National Army in addition to the camps for the National Guard. The building of these National Army camps was begun in June and by September all were ready for troops. As an understanding of the history of disease in the Army during 1917 requires a knowledge of the location and conditions about these camps and cantonments and the source of their troops, leading facts about them are given herewith. For convenience all of the camps situated north of the latitude of the southern boundary of the State of Virginia, are described first, followed by a description of the camps in the Southern States.

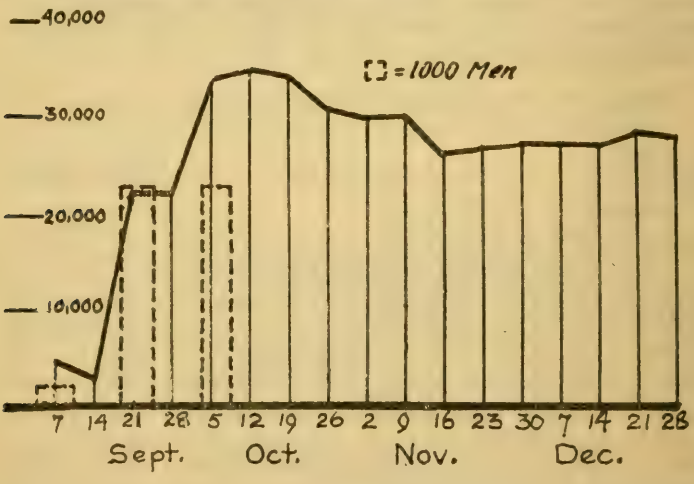
1. CAMP DEVENS, MASS.

Camp Devens is located on an irregular and wooded plateau about 300 feet above sea level just outside of the limits of the village of Ayer (of about 3,000 inhabitants) and approximately 30 miles from the city of Boston. There were natural ponds within the limits of the camp which have been effectively drained. The water supply for the camp is obtained from the Nashua River by a filter basin and the water is chlorinated.

The weather for October, 1917, at Camp Devens was cool, the temperature falling to freezing on the 20th of the month. There was also an excessive rainfall. November was unusually cold and dry. December was the coolest on record, the temperature of the camp falling to about 20° below zero. There was an exceptionally heavy rainfall during the month.

Polygon of weekly strength of Camp Devens, measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP DEVENS

CHART No. 10.

To Camp Devens were called in 1917 from civil life the followin contingents:

	Men.
Sept. 5–10	2, 18
Sept. 19–24	17, 47
Oct. 3–8	17, 47
Total	37, 14

The men came from New England and also from the northeas quarter of New York State. The net quota from Maine was 1,821 New Hampshire, 1,204; Vermont, 1,049; Massachusetts, 20,586 Rhode Island, 2,211; Connecticut, 10,977; New York (part), 5,434 This territory included the large cities of Boston, 750,000 inhabitant of whom about 18,000 are colored; Worcester, 165,000; Fall Rive

130,000; New Bedford, 115,000; Lowell, 114,000; Cambridge, 112,000; Springfield, 105,000; New Haven, 150,000; Bridgeport, 120,000; Hartford, 110,000; Providence, 250,000; and Albany, 105,000. Also numerous cities between 25,000 and 100,000 inhabitants. Of the population of Maine, 51.4 per cent is urban; of New Hampshire, 59.2 per cent; of Vermont, 47.5 per cent; of Massachusetts, 92.8 per cent; of Rhode Island, 96.7 per cent; of Connecticut, 89.7 per cent; of northeastern New York, 52.8 per cent. For the whole territory the percentage of urbanity is 63.7.

The strength of the camp at different dates is shown in Chart 10. As the curve shows, the camp was quickly raised to its full strength of 35,000 men by October 12, and therefore, apparently, few additions by transfer or otherwise were made, so that the strength gradually declined, due chiefly to discharges for disability.

The average monthly strength, all white, is as follows:

	White.
September	20,120
October	26,756
November	26,848
December	26,832

The frequency of the leading infectious diseases at Camp Devens and number of deaths is given by months, as follows:

TABLE NO. 18.—*Admissions and deaths, infectious diseases, Camp Devens, 1917.*

	Admissions.[1]				Deaths.			Total deaths.
	September.	October.	November.	December.	October.	November.	December.	
Lobar pneumonia		8	7	9	2	1	1	4
Broncho-pneumonia		1	8	7		1		1
Measles (uncomplicated)	1	2	33	165				
Measles and lobar pneumonia				1				
Measles and broncho-pneumonia								
Measles and other complications								
German measles		1	8	62				
Mumps		1	6	12				
Scarlet fever				2				
Typhoid fever		1						
Tuberculosis	2	24	28	70				
Cerebrospinal meningitis				3			1	1
Chancroid		3	[illegible]	2				
Syphilis	10	18	24	35				
Gonorrhea	41	45	87	96(1)				
Total	54	104	204	465	2	2	2	[illegible]

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The morbidity rates for December from these diseases, i. e.,

$$\frac{\text{number admissions for selected diseases}}{\text{mean strength}} \text{ is } \frac{465}{26{,}832} = 17.4 \text{ per thousand.}$$

The rate is chiefly due, as we see, to measles and gonorrhea. The camp thus stands in its relation to other states in morbidity in about the same position as in respect to urbanity. During the remainder of the winter the morbidity rate ran about the same as in December and there was no marked epidemic of measles, pneumonia, or meningitis.

The division surgeon reports that the measles was of a very mild type and, as a rule, without complications. Approximately 10 per cent was of the German variety. Overcrowded barracks were a prominent factor in the spread of this disease. As men were transferred away from the division and the strength of organization was reduced to approximately 150 men, the number of cases developing daily showed a perceptible decline, while those organizations that maintained full strength continued to develop new cases. The Twenty-fifth Engineers, whose barracks were greatly overcrowded, were quarantined continuously. In the latter organization three cases of scarlet fever occurred out of a total of nine in the division. One case of typhoid fever, found in a drafted man five days after his arrival at this camp, occurred.

2. CAMP UPTON, N. Y.

Camp Upton occupies about 15 square miles of territory on Long Island between the Atlantic Ocean (5 miles to the south) and Long Island Sound (5 miles to the north). It is about 65 miles from New York City and 5 miles from the rural village of Yaphank. The site was a sandy, slightly rolling country covered with scrub pine. A tributary of the Peconic River, dry except after a rain, traverses the northern part of the reservation; a larger tributary rises in the eastern side. Carmans River runs in a broad shallow valley along the western border. Just south of the reservation are extensive salt marshes, which in August produced swarms of salt-marsh mosquitoes (*Culex sollicitans*) which discouraged workmen and delayed the opening of the camp. The elevation of the camp is about 100 feet above sea level. At a central point a ridge rises about 50 feet above the general level; on this the camp headquarters are placed.

Water is derived from deep-driven wells which tap the remarkable underground water strata of Long Island. Sewage was disposed of by a plant which filtered into the Peconic drainage basin.

The climate is nearly maritime. The mean annual temperature is about 50° F., and the monthly range is from about 74° in July to 30° in January and February. The maximum temperature rarely reaches 95°, the minimum, 0°. The mean annual precipitation is about 45 inches. The weather in the autumn of 1917 was severe. In September the temperature was about 5° below normal; in October, 7° below (mean, 48°); in November, 6° below normal (mean, 37°); in December, 8° below normal (mean, 25° F.), being the coldest December on record. A heavy snowstorm occurred in the middle of the month and on the 30th the temperature touched 7° F. below zero.

On account of the necessity of clearing so much ground and on account of labor trouble (aggravated by the above-mentioned mosquitoes), mobilization at Camp Upton was delayed five days. The successive increments (as called by the Provost Marshal General) were as follows:

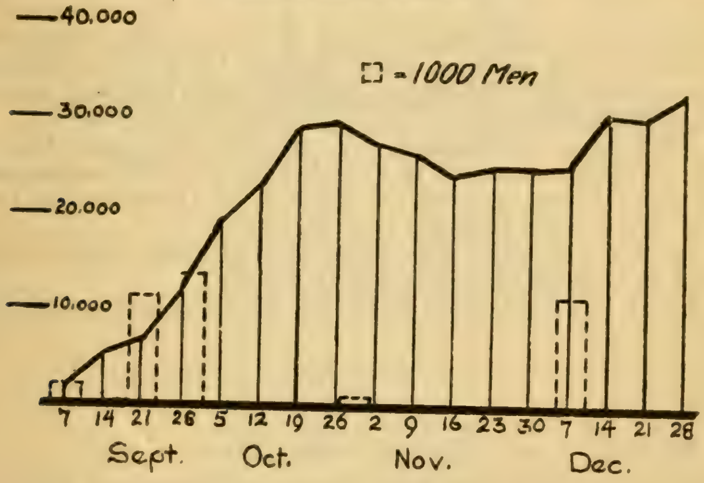
Sept. 10–15	2,112
Sept. 19–24	8,446
Sept. 28–Oct. 2	8,446
Oct. 27–Nov. 1	760
Dec. 5–10	8,446

Thus a total of 28,210 men was ordered to this camp during 1917.

These drafted men came, for the most part, from New York City (including Brooklyn, Queens, and Richmond Boroughs), Long Island and Westchester, Putnam, and Dutchess Counties. Greater New York dominated in this camp, which indeed drew from the most restricted area of any of the military camps. In 1915 Greater New York had a population estimated at 5,468,190, or 16,387 inhabitants per square mile; and Manhattan Borough alone a population of 122,832 per square mile. The population of Greater New York is racially exceedingly mixed. About 24 per 1,000 of the 1,082,000 males, 20 to 44 years of age, were negroes; and 556 per 1,000 were foreign-born whites. Of the total population, 800 per 1,000 are of foreign white stock; about 208 per 1,000 of English or Celtic origin; 185 Yiddish or Hebrew; 183 Germanic; 118 Italian; 47 Slavic and Lettic; 24 Scandinavian; and 14 Magyar. This racial complexity of the population had its influence in the causes of rejection at the cantonment.

Polygon of weekly strength of Camp Upton measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP UPTON

CHART NO. 11.

The leading diseases at Camp Upton had the following frequencies:

TABLE NO. 19.—*Admissions and deaths, infectious diseases, Camp Upton, 1917.*

	Admissions.[1]				Deaths.			Total deaths.
	September.	October.	November.	December.	October.	November.	December.	
Lobar pneumonia	1	6	8	29	1	....	2	3
Broncho-pneumonia	....	1	1	4	....	....	....	....
Measles (uncomplicated)	1	1	6	37	....	....	....	....
Measles and lobar pneumonia	....	....	....	3	....	....	....	....
Measles and broncho-pneumonia	....	....	1	3	....	....	....	....
Measles and other complications	....	....	....	....	....	....	....	....
German measles	....	....	1	....	....	....	....	....
Mumps	1	1	4	55	....	....	....	....
Scarlet fever	....	....	....	2	....	....	....	....
Typhoid fever	....	....	....	....	....	....	....	....
Tuberculosis	5	22	24	32	....	....	....	....
Cerebrospinal meningitis	....	....	1	....	....	1	....	1
Chancroid	1	....	4(9)	8(9)	....	....	....	....
Syphilis	1	16	18(9)	29(28)	....	....	....	....
Gonorrhea	....	41	50(9)	103(18)	....	....	....	....
Total	10	88	145	360	1	1	2	4

[1] Figures in parentheses are used for colored troops in venereal diseases only.

The strength of the camp at different dates is shown in Chart 11. The first 5 per cent of the drafted men were called September 10, and by October 19 the strength had risen (in part by transfers) to 30,000 men. After the December increment the number rose to about 33,000.

On December 28 the noneffective rate at Camp Upton was the lowest of the National Army camps. This is correlated with the fact that the area from which Camp Upton drew is the most densely populated of any in the United States. In one respect the figures for Camp Upton seem high, i. e., in admissions to sick report of gonorrhea. However, in this respect Camp Upton ranks in the middle of the list of all the camps.

3. CAMP DIX, N. J.

This camp lies near Wrightstown, N. J., about 20 miles southeast of Trenton. The site is a sandy plateau 150 feet above sea level, and is well drained. There are, however, large cranberry swamps to the east and south.

The months of mobilization were exceptionally cold. On December 30 the temperature fell to 7° F. below zero. November was dry; there was a heavy snowfall on the 10th of December, so that the ground was covered for some time thereafter.

Camp Dix is supplied with water from artesian wells, which have yielded an abundance of satisfactory quality.

To Camp Dix were called from civil life the following contingents:

	Men.
Sept. 5–10	2,151
Sept. 19–24	17,213
Nov. 24	6,454
Total	25,818

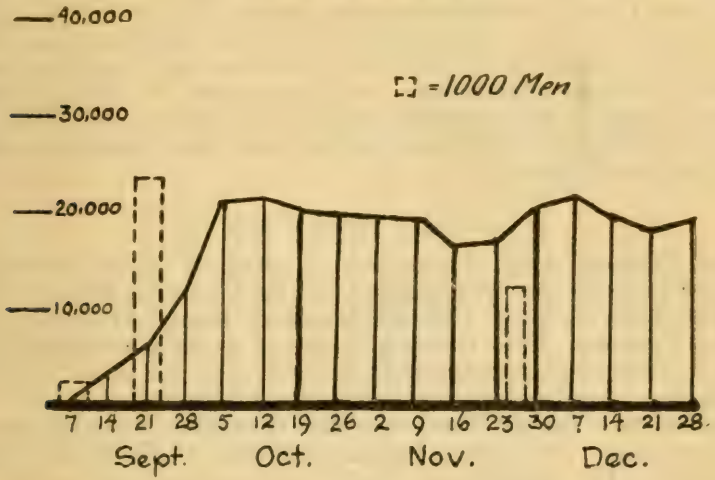
These men came from New Jersey, Delaware, and from all the western counties of New York State and the southern counties that lie west of the Hudson River. The largest cities of this area are Wilmington, population about 100,000; Newark, about 400,000; Jersey City, about 300,000; Paterson, about 140,000; Trenton, about 100,000; Camden, about 100,000; Buffalo, about 450,000; Rochester, about 250,000; Syracuse, about 150,000; Albany, about 100,000. The 26,000 called to Camp Dix came from a territory that is 71 per cent urban.

The strength of the camp at different dates is shown in Chart 12, from its first increment of 2,000 men to the end of the year. As compared with most other camps the total population remained relatively small, about 20,000. There were 671 colored troops at Camp Dix in September and October. These were then transferred away.

The leading diseases at Camp Dix by months are given in the following table. The striking fact is the large number of venereal diseases brought by the new troops. The 14 cases of typhoid fever in October were probably brought by the September increment. Measles were never very frequent—24 cases in December.

Polygon of weekly strength of Camp Dix measured by scale on the left.

Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP DIX

CHART No. 12.

TABLE No. 20.—*Admissions and deaths, infectious diseases, Camp Dix, 1917.*

Total	207	402	284	313	1	1	3	5

---

[1] Here as in other tables the numbers of white and colored patients are distinguished for the venereal disease only. The number of colored is given in parentheses.

The base hospital at Camp Dix was opened October 29, 1917. Up to December 31 there had been admitted 1,313 cases. The average number of days lost per patient, considering all patients, was 12.57. The average number of days lost per venereal patient was 10.5. The following infectious diseases were treated: malaria, 1; typhoid fever, 18; scarlet fever, 4; diphtheria, 2; tuberculosis, 28; tubercular meningitis, 1; chicken pox, 4; mumps, 7; pneumonia, 17; paratyphoid carrier, 1; measles, 18. The head of the hospital suggests: "The fact that the number of infectious diseases in this camp has been smaller than in the western and southern camps is probably largely because this division is comprised of men drawn from more thickly populated centers, where they have been exposed and become immune to many of the usual infectious diseases of camps. The number of cases of pneumonia has been very small, probably because there have been few cases of those infectious diseases which are frequently followed by pneumonia. The division has been well housed and clothed and the climatic conditions are exceptionally good."

4. CAMP MEADE, MD.

This National Army cantonment is situated nearly midway between Baltimore and Washington, on land lying between 100 and 200 feet above sea level. The soil is a sandy loam. It is well drained by the Patuxent River running along the western boundary of the camp. There was some springy ground near the river, and some Anopheles mosquitoes were found in the autumn.

The weather during November and December was exceptionally cold and dry. The lowest temperature was 2° F. on the 30th of December. The ground was pretty well covered with snow from the middle of December.

The water supply consists in part of three driven wells of excellent quality to which, as an auxiliary, is added water from Patuxent River, the latter more or less polluted. By alum precipitation and rapid sand filtration and chlorination this water was rendered usable. Sewage was disposed of by means of the usual septic tank.

To Camp Meade came in 1917 the following contingents:

	Men.
Sept. 19–24	17,882
Sept. 26–30	418
Oct. 3–8	2,035
Nov. 1	4,467
Nov. 2–7	12,108
Total	36,850

These men came from eastern Pennsylvania and Maryland and the District of Columbia. This territory includes the large cities of Philadelphia (1,700,000), Scranton (150,000), Reading (100,000), Wilkes-Barre (75,000), Harrisburg (75,000), Baltimore (580,000), Washington, D. C. (365,000). Taken as a whole the territory from which Camp Meade draws is 68.5 per cent urban, being exceeded in urbanity only by the territories tributary to Camps Upton and Devens.

The strength of the camp at different dates is shown in Chart 13. Beginning with the draft of September the camp grew rapidly to a strength of 23,000 on October 12, then diminished on account of transfers and rose again with subsequent drafts to 33,000. Colored recruits to the number of 2,154 were received in November; there were 3,336 present in December.

The diseases and consequent deaths at Camp Meade during 1917 are shown in Table 21.

Polygon of weekly strength of Camp Meade measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]

Total	33	259	668	775	1	5	8	14

[1] Figures in parentheses indicate number of colored patients in venereal disease only.

The amount of communicable diseases of any sort was small, owing to the relative immunity of the troops, who came largely from cities. Here as elsewhere the proportion of admissions for venereal diseases among the colored recruits was relatively high.

5. CAMP LEE, VA.

The site of Camp Lee is a plateau about 160 feet above sea level. On its western margin it is bounded by the tidal estuary of the Appomattox River. The soil is a sandy loam. The soil drainage is excellent. The camp is situated about 3 miles from Petersburg (of about 25,000 inhabitants) and about 20 miles from Richmond, a city of a population of about 140,000. The upland is well drained; but there are some mosquitoes, probably chiefly from the salt marshes near the mouth of the Appomattox River. The average July temperature is about 78°, that of December is 30°, and of January, 38°. That of October, 1917, was the lowest on record for that month; it fell to 28° on the 31st. Precipitation exceeded the normal. November was unusually cold and dry. In December records for low temperature were broken, the temperature falling to 2° below zero on the 30th.

Camp Lee is supplied with water from Petersburg by means of wooden pipes. The water comes from the river and is chlorinated so that it is quite safe; though the supply eventually proved inadequate. Sewage was disposed of into a tributary of the river, a tidal estuary. This created a nuisance, so that a sewage-disposal plant had to be installed.

Polygon of weekly strength of Camp Lee measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]

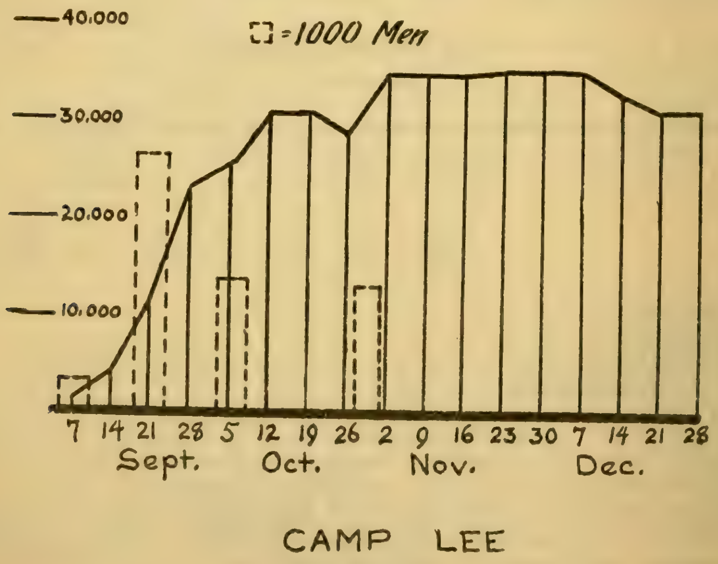

CHART No. 14.

To Camp Lee were called from civil life the following contingents:

	Men.
Sept. 5–10	2,340
Sept. 19–24	18,721
Oct. 3–8	9,748
Oct. 27– Nov. 1	9,050
Total	39,859

These men came from western Pennsylvania, from Virginia, and West Virginia. This territory includes the southern part of the mountain ridges of Pennsylvania, the mountains and valleys of the

Virginias, extensive farm areas in northwest Pennsylvania, eastern Virginia, and western West Virginia. The northwestern counties of Pennsylvania (except Erie) and the mountain counties of this section for the most part average under 50 persons to the square mile. Three-fourths of the counties of West Virginia and Virginia have under 50 to the square mile. The large cities are Pittsburgh (about 750,000), Erie (about 75,000), Richmond (about 140,000), Altoona (about 55,000), Johnstown (about 55,000), Norfolk, Va. (about 75,000), and various other places of 50,000 to 10,000 inhabitants. Thus of the 39,000 men called to Camp Lee a little over one-third came from considerable cities.

The strength of the camp at different dates is shown in Chart 14—from its first increment of 3,000 at the beginning of September to the middle of October, when there were 31,000 at the camp, and on into November, when 35,000 were present. Of the Pennsylvania recruits about 3 per cent were negroes; of the Virginian, about 30 per cent.

The leading diseases at Camp Lee were as follows:

TABLE NO. 22.—*Admissions and deaths, infectious diseases, Camp Lee, 1917.*

Total	62	261	715	1706	1	5	14	20

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

On December 28 the noneffective rate was the highest of any National Army camp with the exception of Pike and Funston.

Measles became epidemic in November, but was complicated by relatively little pneumonia, probably owing both to retention of measles cases in hospital until completely recovered and also to the fine environmental conditions. On the other hand there were a number of middle-ear infections following measles. An epidemic of general streptococcic infections with local manifestations, best defined as a polyserocitis, occurred at the end of the year.

Pneumonia began to increase toward the middle of December; the types were not differentiated until that time. There were only about 11 per cent deaths. Toward the end of December a number of patients were admitted to the hospital with various septic infections, purulent empyema, peritonitis and pyopericardium. In some instances (but not in all) autopsy showed a primary broncho-pneumonia.

Venereal diseases: A large proportion existed prior to enlistment. This was especially noticeable among the colored troops.

6. CAMP TAYLOR, KY.

Camp Taylor is located about 5 miles south of Louisville, Ky., a manufacturing city of 230,000 inhabitants. The terrain is rolling, about 500 to 530 feet above sea level, and drains toward the city. The soil is loam over red clay.

The temperature was abnormally low (as at most other places in the North) during November and December, reaching 6° on the 9th of December. There was a shortage of rainfall, but a heavy snowfall kept the ground covered during most of December.

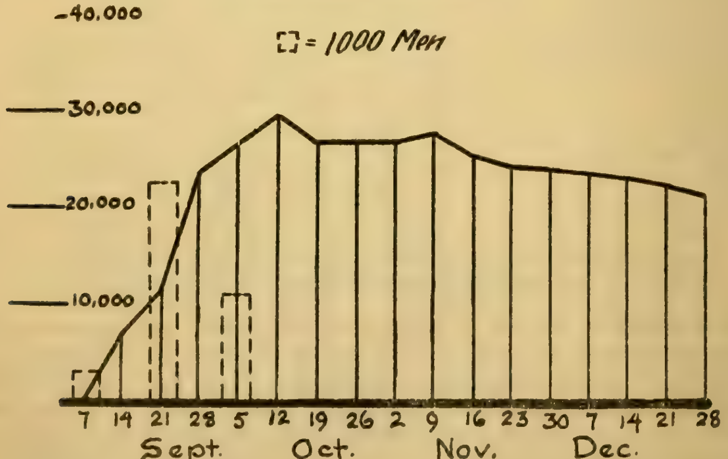
The water supply is derived from the city system. It is taken from the Ohio River and is sedimented, filtered, and chlorinated. It is abundant and excellent in quality. The sewage is disposed of through the city's trunk sewer.

To Camp Taylor were called from civil life the following contingents:

	Men.
Sept. 5–10	2, 117
Sept. 19–24	16, 927
Oct. 3–8	8, 463
Total	27, 507

Polygon of weekly strength of Camp Taylor measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP TAYLOR

CHART No. 15

The men came from Kentucky, Indiana and southern Illinois. This territory included such cities as Louisville (240,000), Covington (60,000), Indianapolis (280,000), Evansville (75,000), Fort Wayne (75,000), Terre Haute (75,000), South Bend (65,000), and Springfield, Ill. (60,000). The territory from which the drafted men came is about 33.7 per cent urban, standing eleventh in the series of urbanity of the 16 National Army camps. The population of Kentucky is 90 per cent white, and 92 per cent of the whites are of native parentage. They are largely of Scotch or Scotch-Irish origin. Of the population of Indiana, all but 2 per cent are white and 78 per cent of these are of native parentage. The foreign white stock is half German, 10 per cent Irish, 7 per cent English and about 7 per cent Austro-Hungarian. In southern Illinois the population is about 90 per cent white of native parentage.

The strength of the camp at different weekly intervals is shown in Chart 15. From its beginning in early September the camp strength rose quickly to 29,000 on the 12th of October and then slowly declined to 21,000 at the end of the year. There were never many colored troops at the camp.

The leading diseases and consequent deaths at Camp Taylor are given in Table 23.

TABLE No. 23.—*Admissions and deaths, infectious diseases, Camp Taylor, 1917.*

Total	200	566	995	702	2	8	13	23

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The principal disease was measles, which likewise caused a heavy morbidity in Kentucky troops at the outbreak of the Civil War. No deaths occurred from measles directly nor from the 7 cases where lobar pneumonia supervened. But from the 43 cases where broncho-pneumonia was a complication to measles 13 deaths followed. Though there were nearly half as many cases of primary broncho-pneumonia as of broncho-pneumonia complicating measles, there were only about one-sixth as many deaths. Primary lobar pneumonia also had only a low case morbidity (6 per cent). It is reported that among 52 empyema fluids, 27 showed a hemolytic streptococcus, 5 pneumococcus, 18 were sterile and 2 not examined. About 9 per cent of all sickness at camp was due to venereal disease.

7. CAMP SHERMAN, OHIO.

Camp Sherman is located in the flood plain of the Scioto River just outside of the limits of the city of Chillicothe, Ohio, a railroad center of 15,000 inhabitants, in an agricultural region.

The soil is sand and gravel, overlaid with a thin stratum of clay. The trend of drainage is toward the river, although in many places the ground is low and required extensive ditching. The proximity of the remount depot to the camps presented a difficult problem in sanitation because of the large amount of manure that required removal and the consequent facilities for fly breeding.

The water supply is obtained from five drilled and one dug well, located near the banks of the Scioto River. All wells are protected from surface drainage and well policed. Water is chlorinated before entering distribution mains. There have been no water-born diseases.

The region of Chillicothe was characterized in November by cool and very dry weather, and in December by the lowest temperature for that month on record, namely 13° below zero on the 11th of the month. The cold spell was exceptionally prolonged. The month was prevailingly dry, but there were heavy snow falls which kept the ground covered nearly all of the month.

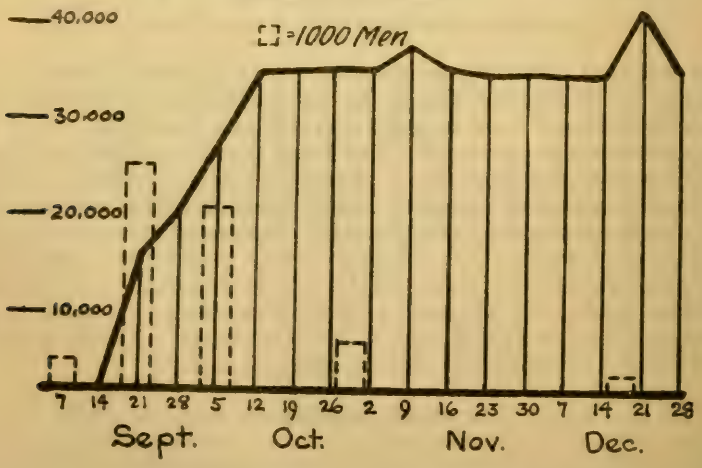
To Camp Sherman were called from civil life the following contingents:

	Men.
Sept. 5–10	2,154
Sept. 19–24	17,233
Oct. 3–8	12,925
Oct. 27–Nov. 1	2,957
Dec. 14–19	892
Total	36,161

These men came from Ohio and a few counties in western Pennsylvania. This territory includes the cities of Cleveland (660,000), Cincinnati (410,000), Columbus (215,000), Toledo (190,000), Dayton (130,000), Youngstown (110,000), Akron (85,000), Canton (60,000), Springfield, Ohio (53,000).

Polygon of weekly strength of Camp Sherman measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP SHERMAN

CHART No. 16.

Taken as a whole the population from which this camp was drawn was 50 per cent urban, being the third from the greatest urbanity of all National Army camps.

The strength of Camp Sherman at different dates is shown in Chart 16. Owing to large increments within the first 30 days the strength rose to 35,000 and remained at about this point until, in the middle of December, it was increased by transfers and a small draft contingent to nearly 40,000. Of this number 2,032 were colored troops, which arrived in November; to these additions were made, bringing the total up to 3,314 colored troops in December.

The leading diseases at Camp Sherman are shown in Table 24.

TABLE NO. 24.—*Admissions and deaths, infectious diseases, Camp Sherman, 1917.*

Total	153	624	684	797	1	7	8	16

[1] Figures in parentheses indicate number of colored troops in veneral disease only.
[2] In the table of "admissions" (Table 48) these cases are charged against the Third Ohio Infantry.

Admissions for gonococcus infection reached 1,140 from September till December, a total exceeded only by Camp Lewis and Camp Travis. All three camps housed a large population not augmented greatly by later draft contingents. Camp Sherman had a relatively high percentage of negro troops, which brought in a disproportionately large number of infections.

An epidemic of measles started in December with 149 cases and did not abate until the middle of January, but it was of a mild type and no pneumonia followed.

Thirteen cases of typhoid fever developed in the cantonment during the year. Of these, 12 cases were in Company H, Third Ohio Infantry.[1] This company arrived at Camp Sherman on August 16 and immediately went into barracks. The company had been in camp at Springfield, Lima, and Tiffin, Ohio, for four and one-half months doing guard duty. A condemned well was near the camp site at Springfield, and the men frequently drank water from this well. All these cases were in men who had not received typhoid prophylaxis, and all developed between August 21 and September 5. One case was contracted at Prospect, Ohio, and the man had received no typhoid prophylaxis. All cases of typhoid fever were transferred to Columbus Barracks, Ohio, for treatment.

---

[1] In the table of "admissions" (Table 48) these cases are charged against the Third Ohio Infantry.

Cerebrospinal meningitis.—Of this disease there were 16 cases and 4 deaths, a mortality of 25 per cent. On November 10 a case of meningitis developed in Company M, Three hundred and twenty-ninth Infantry. At this time equipment was not on hand to do carrier work, but all members of this company were treated by regimental surgeons. On November 8 another case developed in this company. Fifty-four men in the same squad room were examined but no carrier found. On November 8 a case developed in Company A, Three hundred and twenty-ninth Infantry. All men in this organization were examined and two carriers were found, one of whom occupied a bed immediately adjacent to the one occupied by the men who developed meningitis. On November 13 another case developed in this organization. All members of the organization were examined and one carrier found. The remaining 10 cases were all isolated, no 2 of them occurring in the same organization or squad room. All cases of meningitis were placed in isolation to search for carriers. During November, four carriers were found, representing 1.2 per cent of the men examined. During December three carriers were found, representing two-tenths of 1 per cent of the men examined. Four known carriers of meningococcus have been rid of that organism in six days by one treatment per day. There were 10 companies from which cases of meningitis arose, and in these companies no subsequent cases developed after treatment was instituted.

The base hospital service is well organized, manned, and equipped. Up to December 31, 288 operations had been performed of a general surgical character.

Surgery of the eye, ear, nose, and throat, and dental work each had its own out-patient service in a separate pavilion designated as the "head house." This building was eventually very thoroughly equipped with the necessary instruments and appliances for carrying on the work of the different subsections, including a perfectly appointed operating room for eye surgery, and another for nose and throat, and five dental operating rooms, all having access to common waiting rooms for the use of convalescents coming from the various wards, as well as for out-patients.

In the section of ophthalmology the total number of cases examined and treated was 578. The average daily number was 23. Fifty-one of these were treated in hospital, on whom 31 operations were performed. Refractions, 168; glasses ordered, 123. In the section of oto-laryngology 2,789 treatments were given and 140 operations performed. In the subsection of genito-urinary diseases six wards were in use with an out-patient department on three days weekly, treating from 80 to 100 cases per day. Over 1,000 doses of salvarsan were given and an average of about 800 out-patient treatments were given per month. This section was well equipped with the necessary instruments and apparatus incidental to diagnosis and treatment in accordance with the most modern methods, including electrocystoscopy and ureteral catheterizations.

8. CAMP CUSTER, MICH.

Camp Custer is located about 5 miles south of Battle Creek, Mich., a manufacturing city of nearly 30,000 inhabitants. The site of the camp is a rolling plateau at the headwaters of certain streams flowing into the Kalamazoo River, and incloses several lakes. Ground was broken for construction June 27, 1917.

The temperature of the last three months of the year was below the average. A temperature of 16° F. below zero was reached on the 15th of December. November and December had less precipitation than usual. There was a total snowfall of 9 inches during December, and only nine clear days.

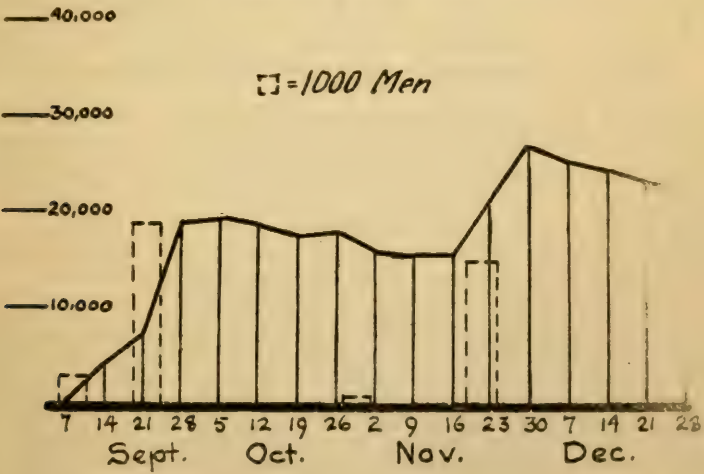
Camp Custer is supplied with water from eight wells, driven through terminal glacial deposits into sandstone. These wells have a capacity of 4,800,000 gallons in 24 hours, and the water is of excellent quality. The sewerage disposal system is of the Imhoff type, of which the affluent, after being treated with chlorine, is allowed to flow into the river.

To Camp Custer were called from civil life the following contingents:

	Men.
Sept. 5–10	1,800
Sept. 19–24	14,394
Oct. 27–Nov. 1	526
Nov. 19–24	10,796
Total	27,516

Polygon of weekly strength of Camp Custer measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP CUSTER

CHART NO. 17.

These men came from Michigan and the eastern rows of counties of Wisconsin, including especially the city of Milwaukee, 440,000 inhabitants. The chief Michigan cities are: Detroit, about 600,000 inhabitants; Grand Rapids, about 130,000; Saginaw, about 55,000; Flint, 55,000; and Bay City and Kalamazoo, each about 50,000. Of the whole territory from which the camp drew, the percentage of urbanity is about 53.

The strength of the camp at different dates is shown in Chart 17, from its first increment of 1,800 early in September to the end of the year. It rose quickly to 18,000 by the end of September; then gradually declined until the large increments of November 19 to 24 of nearly 11,000 brought the strength to its maximum for the year of 26,000. There were about 380 colored troops in the camp during December.

The leading diseases at Camp Custer are shown in Table 25:

TABLE NO. 25.—*Admissions and deaths, infectious diseases, Camp Custer, 1917.*

	Admissions.[1]				Deaths.
	September.	October.	November.	December.	
Lobar pneumonia	1	9	7	12	None.

Gonorrhea	17	122(1)	270(38)	120(15)	
Total	43	276	587	517	

[1] Figures in parentheses indicate number of colored troops in venereal diseases only.

Most of the 29 cases of lobar pneumonia treated were severe, with two or more lobes involved. As early as laboratory facilities were available, pneumococcus types were determined. In the eight cases so studied up to December 31, 1917, type II was found in four, type IV in four. Thus far, no case of type I was found.

Measles became epidemic in November and German measles acquired important figures. The division surgeon reports:

> The cubical system, using suspended sheets, was put in use in the measles wards, December, 1917. Complications in measles were rare up to the latter part of December, 1917. Three cases developed otitis media, in one of which a mastoid required operation. There were no deaths. With the advent of colds, acute bronchitis, pharyngitis, and tonsillitis in the cantonment, a number of more serious complications have appeared in measles patients since January 1, 1918. The clinical course of these cases resembles that described in "measles pneumonia" in southern camps. The first case was a soldier three weeks after measles, with onset while he was being held sick in quarters after discharge from the hospital. The onset resembled a pneumonia, and pus was discovered by exploratory puncture after several days of illness. Operation was attempted, but the patient died. Autopsy showed that the entire process was not in any case a true lobar pneumonia but began as a streptococcus pleurisy, with an immediate empyema. Since this case all patients have been studied with the special object of detecting empyema early and instituting drainage by operation. At the date of this report (January 15) empyema has been found in 10 such cases, of which 8 were drained, 1 died, and 7 remained under treatment.

In three autopsies with empyema, the findings have been essentially the same, with hemolyticus streptococcus as the bacteriological cause in one case, and purulent peritonitis accompanying the empyema. It seemed possible that the peritonitis was simultaneous with, and not consecutive to, the empyema. The clinical course and pathology of these cases resemble that of certain cases seen in the severe epidemics of septic sore throat which occurred in several of our larger cities during the past winter. These cases have not been confined to patients suffering with measles, but have occurred in other soldiers, following tonsillar abscess or apparently beginning as a primary pleurisy with the pharynx and throat as possible infection atria.

It is believed that the forms of measles and pneumonia hardly express the sequence of events as a whole and that the large number of such cases of measles patients represent rather the development of an independent streptococcus infection quite general in distribution in camps, in a group of patients whose resistance has been depressed by measles.

9. CAMP GRANT, ILL.

The site of Camp Grant is an attractive one. It lies on a plain 20 to 30 feet above the Rock River, from 1 to 4 miles south of Rockford, Ill., a city of about 50,000 inhabitants, the third manufacturing city in the State. The altitude is about 72 feet above the sea. A broad flood plain at the junction of the Kishwaukee and Rock Rivers forms a fine ground for maneuvers. The upland is well drained; nevertheless, there are many small ponds, in some of which mosquito larvæ of the genus Anopheles have been found breeding.

The average July temperature is 73° F. with a maximum of 100° F. or more; that of January about 21° F. The month of December, 1917, was the coldest in many years, the thermometer falling to 15° below zero on the 15th of the month. The snowfall was somewhat above the average; there were 17 clear days.

Camp Grant is supplied with water from six wells at the flood plain of the river, west of the northern part of the camp. These wells reach a depth of about 153 to 185 feet. They yield pure water from below 140 feet. They have supplied over 2,000,000 gallons of water per day.

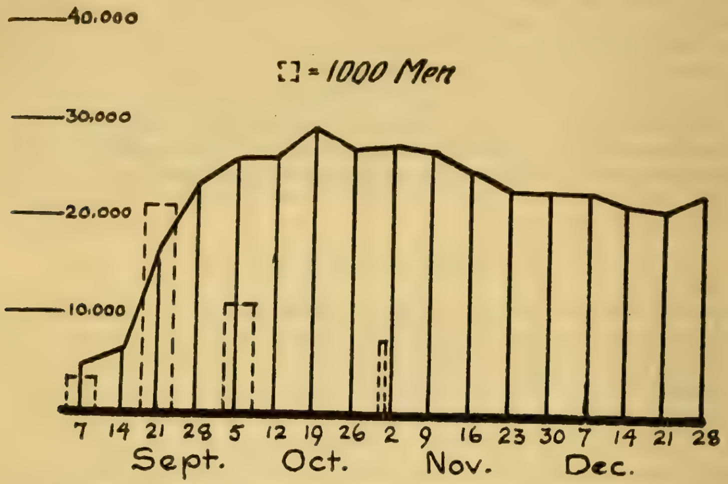
To Camp Grant were called from civil life the following contingents:

	Men.
Sept. 5-10	1,945
Sept. 19-24	15,557
Oct. 3-8	7,780
Nov. 1	1,061
Total	26,343

These men came largely from the 86 local boards of the city of Chicago; and also from the three northern tiers of counties of Illinois and from all the counties of Wisconsin, except those bordering on Lake Michigan. This territory includes in Illinois, besides Chicago (a city of about 2,000,000 whites and 59,000 colored), also Aurora, 35,000, and Rockford, 50,000. In Wisconsin it includes Superior, 45,000; Oshkosh, La Crosse, and Madison, each between 40,000 and 30,000; and smaller cities of about 10,000 inhabitants each. Of the 26,000 men called to Camp Grant about 75 per cent were from cities of over 10,000 inhabitants and about 64 per cent of all from Chicago proper or 71 per cent from Cook County, Ill. Thus the camp population was of prevailingly urban origin.

Polygon of weekly strength of Camp Grant measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP GRANT

CHART NO. 18.

The strength of the camp at different dates is shown in Chart 18. From its first increment of 2,000 on September 10, it rose to 22,000 by September 28, and to a maximum of about 30,000 by October 19. Since the Provost Marshal General called only 25,000 men, it is clear that a few troops were transferred from elsewhere. Chiefly through transfers and discharges the strength of the camp fell to about 21,000 near the end of the year. About 1,000 colored soldiers were inducted into the camp in November.

The leading diseases at Camp Grant had the following frequency:

TABLE No. 26.—*Admissions and deaths, infectious diseases, Camp Grant, 1917.*

[1] Figures in parenthesis indicate number of colored troops in venereal disease only.

On December 28 the noneffective rate at Camp Grant was given as next to the least among the National Army camps. The least place was held by Camp Upton. Thus in these two camps the noneffective rate was in order of the size of the cities from which they drew their population. It may be noted that the rise in admissions to sick report from measles followed shortly after the negro troops entered the camp.

The base hospital at Camp Grant was opened officially August 12, 1917, using an infirmary building in zone 1, with a total of 10 patients, 5 of whom were venereal. The equipment consisted of a camp hospital of 24 beds, but as it was evident that the base hospital would not be in readiness for a month or more the camp-hospital equipment was supplemented by a field hospital, and on August 31 there were 9 patients in the hospital, including 1 pneumonia case and 1 venereal.

At the base hospital great difficulty was experienced in obtaining a satisfactory mess officer and an adequate number of cooks. The schools for cooks and bakers came to the aid of the hospital in emergencies.

10. CAMP DODGE, IOWA.

Camp Dodge is situated on a sandy ridge, about 2 miles from the Des Moines River and about 10 miles northwest of Des Moines, a city of about 100,000 inhabitants, the capital city of the State of Iowa and the center of a great agricultural country. The camp is connected with the city by an electric line. The soil is sandy and well drained.

The temperature of the last months of the year was nearly average, although the temperature fell to 17° below zero on the 29th of December. A snowfall of 11 inches during the month kept the ground covered a large part of the time.

Camp Dodge is supplied with water from driven wells. The water is chlorinated and of a very good quality. The sewage flows into the standard septic tank and the effluent discharges into a nearby stream.

To Camp Dodge were called from civil life the following contingents:

	Men.
Sept. 5–10	2, 258
Sept. 19–24	18, 066
Oct. 27–Nov. 1	3, 855
Total	24, 179

These men came from Iowa, Minnesota, North Dakota, and a zone across the middle of Illinois, north of Springfield. This area included the cities of Minneapolis and St. Paul, together over 600,000 inhabitants; Duluth, about 100,000; Des Moines, about 100,000; Sioux City, about 50,000; Davenport, about 45,000; and five other cities of over 25,000 inhabitants in Iowa; Peoria, 70,000; East St. Louis, 70,000; Quincy, 37,000; and four other cities of over 25,000 inhabitants. Taken as a whole the population was over 32 per cent urban.

The strength of the camp at different dates is shown in Chart 19. Formally opened on August 25 it leaped to nearly its maximum strength of 23,000 by the 28th of September, and thereafter slowly declined. In November many were transferred to other cantonments. In October there were 238 colored troops, in November 3,659, and in December 3,917.

The leading diseases at Camp Dodge are shown in the Table 27.

Polygon of weekly strength of Camp Dodge measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The most striking figures in the preceding table are those for the venereal diseases. Of these the camp surgeon states:

> A high percentage existed on arrival and it was obvious that many of these men had deliberately contracted them or had neglected treatment of old infections under the impression that these conditions would be considered as causes of rejection and

exemption from service. Just after the increment of September 19 came in a venereal survey was made, when it was found that 24 per 1,000 were infected with venereal diseases. The rate would have been much greater if a more careful investigation had been practicable as few syphilitics were detected. However, we are convinced that our young men in civil life are infected with venereal diseases to a greater degree than the Army or Navy ever is. Our rates go up with the advent of new men and decrease in the intervals.

Measles began to appear in October, increased through November and December, and thereafter gradually diminished. Only a few cases of hemorrhagic type were observed and pneumonia as a complication was detected in only a few cases.

Pneumonia, primary and mostly of the lobar type, became prevalent in October; this caused seven deaths. The division surgeon ascribes the high incidence of this disease to inadequate clothing during the cold weather of October, to inadequate heating facilities, and to lack of warm water for bathing. The deaths from pneumonia were mostly among colored troops of the Three hundred and sixty-sixth Infantry.

Mumps reached a high rate for a northern camp. Half of the cases were in the colored regiment.

Of meningitis, from which the camp has been comparatively free, the division surgeon reports:

> Epidemic cerebrospinal meningitis has given us no trouble. Carriers were promptly removed to the hospital and retained until three negative cultures were obtained. No carriers developed the disease and no relation could be established between detected carriers and cases with the disease. All cases entering the base hospital were of a very severe type, the majority on entrance were in a comatose condition. The serum has been given promptly, and at 12-hour intervals during the first few days. The mortality, however, has been high. It is difficult to account for this mortality, except on the basis of inactivity of the serum, as until recently we were unable to obtain the Rockefeller serum.

11. CAMP FUNSTON, KANS.

Camp Funston is located on the left bank of the Kansas River about 5 miles from Junction City (a town of about 6,000 inhabitants) and about 2 to 3 miles beyond Fort Riley. The barracks are built on the flood plain of the river, and the department headquarters on the northwest slope of the river valley. The soil is a fine loam or river deposit. The surrounding country is well drained and without standing ponds or marshes. The elevation is about 1,000 feet above the sea.

The July temperature frequently reaches 100° and has reached 115°, and in January the temperature usually falls below zero and it has fallen to 25° F. below zero. In December, 1917, the lowest temperature was 10° below zero and the mean for the month was 6° below the normal. There was no precipitation, but only 11 clear days.

The water supply is obtained from driven wells, which showed some signs of contamination; consequently the water has been treated with chloride of lime. The sewage of the camp is discharged into the river, a procedure justified by the considerable distance to the next city below the camp.

To Camp Funston were called in 1917 from civil life the following contingents:

	Men.
Sept. 5–10	2,327
Sept. 19–24	18,606
Oct. 3–8	17,306
Nov. 1	1,597
Total	39,836

These men came from Kansas, about 5,600; Missouri, about 16,000; Nebraska, about 7,100; South Dakota, about 2,300; Colorado, about 4,200; New Mexico, about 2,000; and Arizona, about 3,000. All of these came from rural communities save St. Louis, about 4,000; Kansas City, about 800; Omaha, about 1,000; Denver, about 310; and Pueblo, about 370. Altogether about 6,480, or 16 per cent of the population of the camp, was urban in origin. Thus the camp population was prevailingly of rural extraction.

The strength of the camp at different dates is shown in Chart 20. Its first increment of 2,000, which entrained from the 5th to the 10th of September, was slow in arriving (on account of great distances to be traveled) and was tardily counted. A call for 25,000 was followed by a second call in two weeks for 23,000, so that by the middle of October about 44,000 men and officers were in the camp, of whom 147 were colored. A meningitis outbreak occurred at the end of October, increased to 20 new cases in the week ending November 23, and then decreased. Meanwhile the crowding in the camp was relieved by transfer until the strength of the camp fell to about 25,000 at the end of the year.

Polygon of weekly strength of Camp Funston measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the smal rectangle above the polygon.]

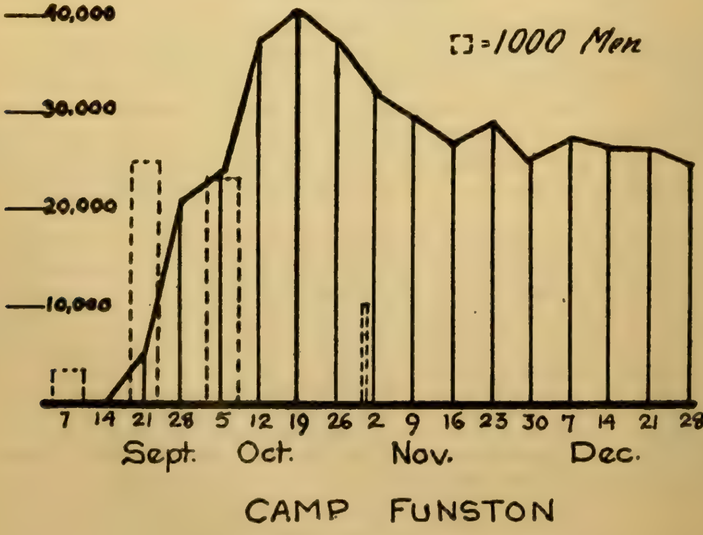

CHART No. 20.

The frequency of the leading infectious diseases at Camp Funston was as follows:

TABLE NO. 28.—*Admissions and deaths, infectious diseases Camp Funston, 1917.*

Total	82	809	380	197	7	20	10	37

[1] Figures in parentheses indicate number of colored troops in venereal diseases only.

For the week ending December 21, weekly report, the noneffective rate at Camp Funston was given as the highest of any camp for that week. The diseases which caused most concern, because exceptionally high, were, first, the cerebrospinal meningitis, of which the revised figures give 16 admissions in October, 21 in November, and 1 in December, with a total of 11 deaths from this fatal disease. Secondly, measles which first became prevalent at the opening of November, increased to 338 cases during the week ending December 28, and soon thereafter decreased. Pneumonia, which so often in the camps follows upon measles, did not reach the large figures that appeared in Camps Travis and Bowie (February, 1918). Though the death rate was high in December it did not reach half that of some of the southern camps. To summarize: infectious diseases spread at Funston in the explosive fashion characteristic of camps full of a rural, nonimmune population. But there was something about conditions, or perhaps the type of measles, which prevented heavy onset of pneumonias, following measles.

The conditions that accompanied the epidemics of meningitis and measles at Camp Funston were carefully studied. The Surgeon General called attention to the fact that the territory which was tributary to the camp was a notorious meningitis center. Apparently through some sort of miscalculation, the camp was crowded far beyond its capacity, in consequence of exceptionally large increments, following each other closely. Soldiers slept in upper and lower bunks with far less than the standard 500 cubic feet of air space to a man. The month of all this crowding was the coolest October on record, the temperature falling to 8° F. below freezing. There was a great shortage of warm clothing and blankets. The ground was extremely dry and a fine dust from the silt of the flood plain filled the air and aggravated the bad situation. November was dry but not so unseasonably cold as October, which may account for the temporary drop in the number of new cases of measles toward the end of November.

December was exceptionally dry and cold. Thus meteorological conditions tended to exaggerate the symptoms of danger of contact of soldiers and thus to facilitate the spread of measles.

12. CAMP LEWIS, WASH.

Camp Lewis is situated at American Lake, approximately 13 miles south of Tacoma, a city of about 110,000 inhabitants. The soil is porous, absorbing all surface drainage. The water is supplied from great springs, of which the largest has a capacity of 3,500,000 gallons. Two wells have a pumping capacity of 1,140,000 gallons together. The water is of excellent quality. The sewage passes by gravity into Nisqually Bay, a branch of Puget Sound.

The western part of Washington has an equable climate. The lowest temperature for December was 28° F. There was a rainfall that month of 15.3 inches, above double the average, and practically no snow fell. There was only one clear day. The "constant cold rains" aggravated certain throat inflammations.

To Camp Lewis were called from civil life the following contingents:

	Men.
Sept. 5–10	2, 275
Sept. 19–24	18, 184
Oct. 3–8	18, 185
Oct. 27–Nov. 1	456
Nov. 2–7	6, 363
Total	45, 463

Polygon of weekly strength of Camp Lewis measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]

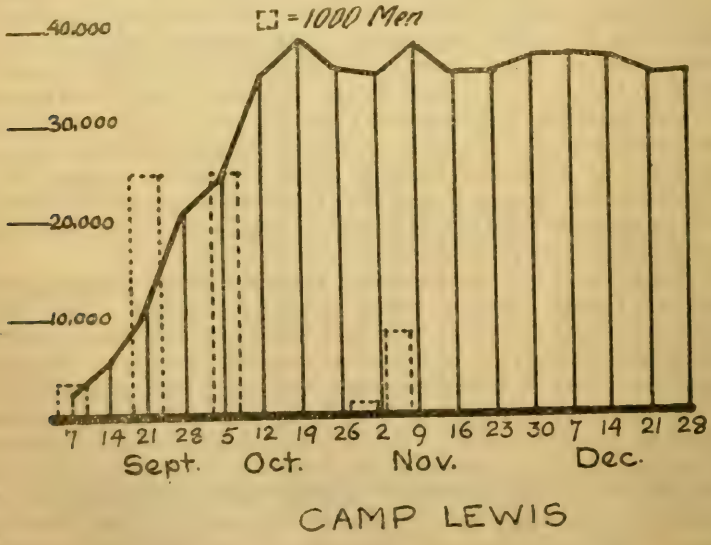

CHART No. 21.

These men came from Washington, Oregon, Idaho, Montana, Wyoming, Utah, Nevada, and California. This area includes such cities as Seattle (340,000), Spokane (145,000), Tacoma (110,000), Portland (275,000), Butte City (145,000), Salt Lake City (115,000), Ogden (35,000), Los Angeles (480,000), San Francisco (460,000), Oakland (200,000), Sacramento (65,000), Berkeley (55,000), and San Diego (53,000), besides numerous smaller cities, especially in California. Taken as a whole, the territory from which Camp Lewis draws is 51 per cent urban or about the same as Camp Custer.

The strength of the camp at different dates is shown in Chart 21. Owing to huge increments of the latter half of September and early October the population mounted quickly to nearly 40,000 by October 15, and then slowly fell to 35,000 by the end of the year. The colored troops numbered about 500 during October, November, and December.

The leading diseases at Camp Lewis are shown in Table 29.

TABLE NO. 29.—*Admissions and deaths, infectious diseases, Camp Lewis, 1917.*

	Admissions.[1]				Deaths.			Total deaths.

Gonorrhea	342(1)	1,018(2)	365(2)	129(1)				
Total	419	1,318	771	1,548	3	8	3	14

[1] Figures in parentheses indicate number of colored troops in venereal diseases only.

The most striking feature of this table is the great number of cases of German measles (1,063 in December). In respect to the frequency of this disease the camp stands in a class by itself. Typical measles, on the other hand, was relatively infrequent. Camp Lewis had also the largest number of new admissions for gonorrhea of any camp (among the recruits of October). This exceptional rate for venereal disease was not maintained in later months. The division surgeon reports: "Arriving men showed a large percentage (2.73 per cent) of venereal disease, and it was decided to place all in camp hospital, the milder cases being sent to duty soon but continued under treatment." This undoubtedly accounts for the large number of venereal cases admitted to sick report in October and November. It is to be recalled also that the population was drawn largely from mining regions.

This camp was also visited by a small epidemic of scarlet fever, with no deaths reported. The division surgeon reports that nose and throat cases were so numerous that, while waiting in the outpatient clinic of the base hospital, patients with sore throats, beginning scarlet fever, were seated next to the patients with sore throat, beginning measles and other infectious diseases. Cross infections occurred, and it was thereupon ordered that all but emergency nose and throat cases should be treated at regimental infirmaries. Up to that time about 300 operations on hypertrophied tonsils alone had been performed.

Pneumonia.—As draft men arrived in successive contingents, efforts were made to secure floor and air space as ordered from Washington. Thus the incidence of pneumonia was undoubtedly controlled, since every other draft man promptly caught cold, particularly those coming to a cold, wet climate from warm, dry States. First cases of pneumonia were almost exclusively from dry, warm climates. The mortality rate remained low, although laboratory personnel were too fully engaged to attempt to divide pneumonia cases into groups. Nevertheless, No. 1 serum was occasionally used.

13. CAMP JACKSON, S. C.

This camp is situated about 5 miles from Columbia, S. C., the State capital, a city of about 30,000 inhabitants. The terrain is sandy and rolling, draining both to the southeast and northwest. A large swamp adjoining the western boundary of the camp and covering about 300 acres is traversed by Gill Creek. Another swamp on the camp site proper forms the headwaters of Wild Cat Creek. This had to be drained. Construction of the camp was begun on June 15, 1917, at which time the whole camp site was covered with woods and cotton fields. During the months of July and August, 1917, the contractor used between 7,000 and 10,000 men daily building barracks and clearing land.

The weather at Jackson was abnormally cool during September to December, 1917, and fell to 8° F. on December 30. The temperature fell to freezing during 21 days of the month. The autumn was dry. A snowfall of 2 inches occurred on the 12th of December.

Water is obtained from the city of Columbia. As the water supply came from a contaminated source and the filter beds were not functioning properly, it was chlorinated. A permanent sewage disposal plant was built, of which the effluent discharged into a small creek.

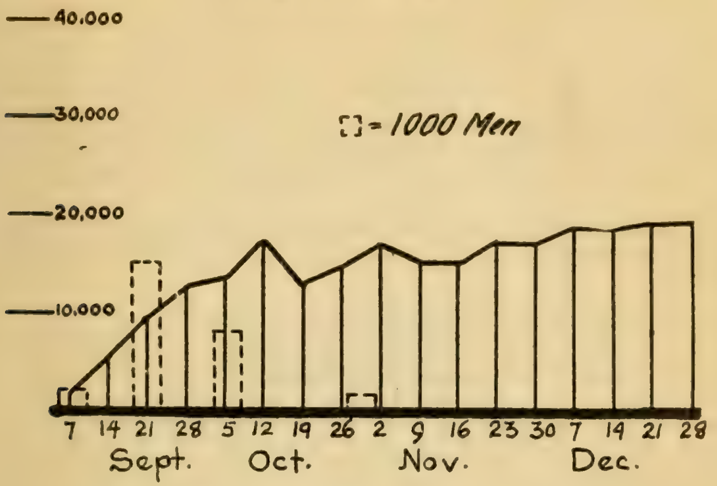
To Camp Jackson were called from civil life the following contingents:

	Men.
Sept. 5–10	1,619
Sept 19–24	10,858
Oct 3–8	5,407
Oct. 27–Nov. 1	1,008
Total	18,892

The men came from North Carolina, South Carolina, and Florida, whose combined quota amounted to 32,380. This territory comprises in North Carolina, 7 cities of over 10,000 inhabitants (largest, Charlotte, 40,000); in South Carolina, 5 cities of over 10,000 inhabitants (largest, Charleston, 60,000); in Florida, 4 cities of over 10,000 inhabitants (largest, Jacksonville, about 70,000). The territory drawn from is only about 17.5 per cent urban. Indeed this camp shows the smallest percentage of inhabitants from cities of any of the National Army cantonments.

Polygon of weekly strength of Camp Jackson measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]



CAMP JACKSON

CHART No. 22.

The strength of the camp at different dates is shown in Chart 22. From its first increment of 1,600 men in September it increased gradually, reaching a maximum of about 19,000 at the end of the year. 2,642 colored men entered the camp during October, 1,017 during November, and 2,266 during December, or a total of 6,325.

The leading diseases at Camp Jackson were as follows:

TABLE No. 30.—*Admissions and deaths, infectious diseases, Camp Jackson, 1917.*

	Admissions.[1]				Deaths.			Total deaths.
	September.	October.	November.	December.	October.	November.	December.

Total	134	400	1,618	962	1	36	50	87

[1] Figures in parentheses indicate number of colored troops in venereal diseases only.

The most striking facts shown by this table are the great numbers of cases of measles, German measles, and mumps. The number of cases of tuberculosis was also relatively great and in December cerebrospinal meningitis had risen to the proportions of a great epidemic exceeding that experienced at any other camp. The epidemic burned itself out during the following two months. The reason for this epidemic is the nonimmunity of the rural troops. It is stated that meningitis appeared in the families of the workmen engaged in building the barracks at Camp Jackson before the troops began to assemble.[1] Of the men who had meningitis at this camp 31 per cent died.

As bearing on the epidemic of measles and meningitis in Camp Jackson the following statements are quoted from the report of the Division Surgeon:

> The hospital buildings were inadequate and incomplete even by the end of the year. Woolen clothing was available, but many men did not have it and were seen going about in cotton clothing in spite of freezing weather. The lack of warm clothing is probably promoting the transmission of disease by causing the men to congregate indoors and about stoves, but we did not hear complaint of suffering. The enlisted personnel of this camp seems to show an unusual amount of illiteracy, general ignorance, and ignorance of personal hygiene, all of which doubtless has aided in the propagation of disease. The enlisted personnel is, of course, mainly rural in origin and contains a relatively large proportion of men who have not had measles or mumps in childhood. In addition to those men, certain contingents have come from Camp Gordon and Camp Pike, and it appears that these were a potent factor in the introduction and spread of disease among susceptible men.
>
> *Pneumonia.*—Here, as in other camps, the prevalence of measles has been a principal factor in the causation of pneumonia. It is probable that considerably more than 40 per cent of all the cases of pneumonia accompanied or followed measles. The prevailing pneumonia at Camp Jackson was broncho-pneumonia, and the majority of these cases were consecutive to measles, and these were far more fatal than ordinary lobar pneumonia.
>
> The factors to be considered in the causation of pneumonia at this camp have been much the same as at other camps, with less overcrowding and less dust. Measles has been prevalent; the men did not have sufficient supply of warm clothing until recently and even now there is some deficiency. There has been trouble with the heating arrangements, and the cold set in early and was unusually severe for this climate. Hookworm infestations are widespread.
>
> *Measles.*—The total number of cases of measles was, to December 31, 1,452. The disease gained in September but did not assume epidemic proportions until the last week of October. It reached its maximum in the week ending November 23, when 528 new cases entered the hospital. Three deaths have been attributed to measles in addition to those dying of broncho-pneumonia.
>
> *Meningitis.*—Epidemic cerebrospinal meningitis made its appearance in this command November 15, 1917, and appeared in the person of a man coming to this camp from Camp Gordon. In November there occurred 20 cases, December 106 cases, and these two months give a total of 37 deaths from this cause. Epidemic cerebrospinal meningitis was certainly transferred to this division from Camp Pike, Little Rock, Ark., which began to send draft men here in November, 1917. Likewise cases occurred in men arriving here from Camp Gordon. In the case of men transferred from Camp Pike two men were removed from the train with fully developed cases of epidemic cerebrospinal meningitis present upon their arrival. It is certain that this infection came, at least in part, from these two sources of Camp Pike and Camp Gordon. From a study of the local situation it appears probable that the measles ward in the base hospital was a contributing factor to the spread of this disease in this camp, as in a well-recognized percentage of cases men coming from uninfected area of camp and being sent to the hospital would first develop measles at the hospital, recover from measles, and in the course of 14 to 16 days return to duty, after returning to duty develop meningitis within one to three days after their return, there being no other case of this disease in their companies. At least 24 of the early cases contracted the disease in the measles ward.

---

[1] Vaughan and Palmer, 1918.

Venereal diseases.—These were nearly all brought in by recruits. Of the infections got by men already in the service seven were contracted in October, seven in November, and five in December.

14. CAMP GORDON, GA.

Camp Gordon is located at Chamblee, Ga., within 10 miles of the capital city of Atlanta (154,839). The region is agricultural and is on the edge of the black belt of the State. The ground of the cantonment is naturally rolling, with some turfed and wooded areas. Prior to occupancy by the Government the site was dotted over with unsanitary farmhouses, barns, and outbuildings, from which wells and streams were contaminated and around which were numerous breeding places for flies. These unsatisfactory conditions were remedied during the construction of the camp by tearing down all old buildings, closing polluted wells, placarding streams, burning over and plowing under suspected places, and thoroughly policing the entire area.

The water supply is obtained from Atlanta, being delivered to the camp through an 18-inch main. The city supply is taken from the Chattahoochee River, sedimented in large impounding areas, and made fit for use by treatment. The sewage plant consists of the standard septic tank, sprinkling filters, and secondary sedimentation tanks. It worked unsatisfactorily. One menace to the health of the camp was the unsanitary condition of the cheap lunch and soft-drink stands in the village of Chamblee.

November at Camp Gordon, though colder than is usual for the region, was a pleasant month, with 16 clear days. Temperature ranged from 73° on the 8th to 25° on the 25th. December had the lowest temperature rate for that month, recorded in Georgia for 40 years. Temperature ranged from 68° on the 2d to 8° on the 9th. Rainfall was greatly below normal; there was but a slight snowfall. There were 17 clear days.

To Camp Gordon were called from civil life the following contingents:

	Men.
Sept. 5–10	1,923
Sept. 19–24	12,106
Oct. 3–8	7,271
Total	21,600

These men were from the States of Georgia, Tennessee, and the southeastern counties of Alabama. The territory included Atlanta (154,839), Memphis (131,105), Nashville (110,364), Savannah (65,064), Augusta (41,040), Chattanooga (44,604), Macon (40,665), Montgomery (38,136), and Knoxville (36,346). Taken as a whole the territory from which Camp Gordon drew its men is 18.5 per cent urban, ranking next to the last of the cantonment areas in order of urbanity.

The strength of the camp at different dates is shown in chart 23.

The population was extremely irregular, falling off abruptly in October and then rapidly increasing by transfers to a maximum of 38,000 in the middle of December, after which it abruptly declined again. Approximately 1,700 colored recruits entered the camp in October; there were 700 remaining in December.

Polygon of weekly strength of Camp Gordon measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]

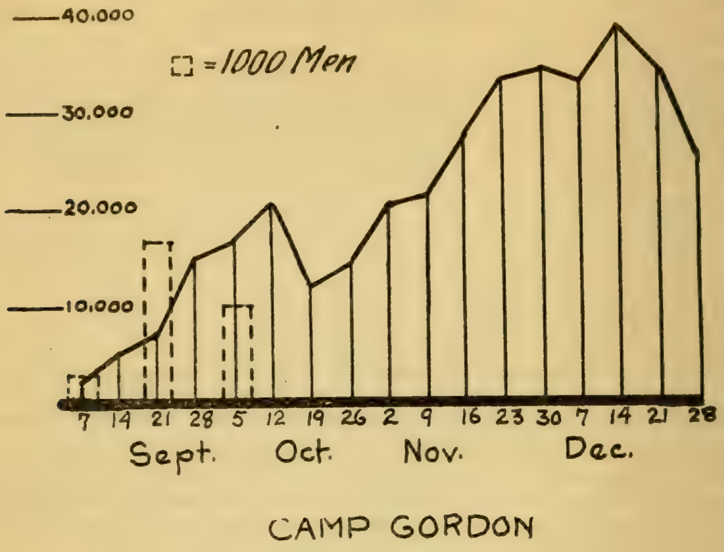

CHART NO. 23.

The leading diseases at Camp Gordon are shown in the accompanying table:

---

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

Gonorrhea was responsible for the largest number of disease admissions from September to December, with measles ranking next. Camp Gordon stood fifth in the rate of incidence of both these diseases. Out of 285 new cases of venereal disease (the camp sanitary inspector reports) 259 were contracted prior to entering the service The measles epidemic reached 495 cases in December and did not begin to decrease until the middle of January. At first it was regarded as of a mild type, little complicated by pneumonia, but at the end of December and still more in January pneumonia following measles increased in frequency and fatality. At the end of the year clothing was still insufficiently supplied. Meningitis never reached such an alarming frequency as at Camp Jackson and the mortality was low. The cases were widely scattered throughout the camp. Every effort was made to secure early recognition of the disease and inspection of contacts. German measles was troublesome, totaling 114 cases in December. Admission of tuberculosis in December exceeded those of any other National Army cantonment except Camp Dodge.

15. CAMP PIKE, ARK.

Camp Pike is situated about 3 miles from the city of Little Rock, Ark., on a plateau 500 feet above sea level, between the Arkansas River and Five Mile Creek.

The weather at Camp Pike was dry and mild during November, 1917. In December it was exceptionally dry and cold; a temperature of 5° was reached on the 9th of the month and there were 12 clear days. There were no snowfalls.

The water supply of Camp Pike comes from the city of Little Rock. It is a mixture of clarified water from the Arkansas River and wells, the latter being used when the Arkansas River supply needs to be diluted on account of excess of sodium salts. The sewage was discharged into a septic tank and effluent ran down the bed of a small creek.

To Camp Pike were called from civil life the following contingents:

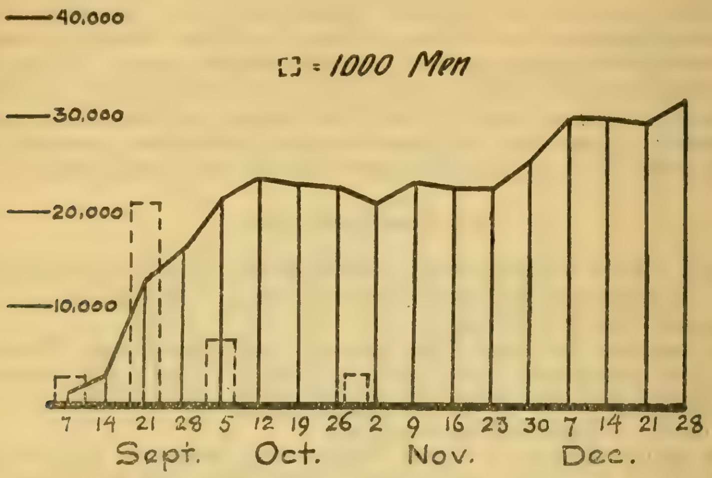
	Men.
Sept. 5–10	2,133
Sept. 19–24	15,755
Oct. 3–8	4,701
Oct. 27–Nov. 1	2,385
Total	24,974

These men came from the States of Arkansas, Louisiana, Mississippi, and the western part of Alabama. This territory includes Little Rock (50,000), Fort Smith (30,000), New Orleans (370,000), Shreveport (30,000), Meridian (25,000), Birmingham (150,000), and Mobile (60,000). Taken as a whole, the territory from which Camp Pike draws is 20.3 per cent urban, being near the last in rank of urbanity.

The strength of the camp at different dates is shown in Chart 24. The rise of strength was varied until October 12, when there were nearly 24,000 troops in camp. Most of the original command, consisting, as we have seen, of men drawn from a rural territory, was sent to southern militia camps as the epidemic of measles became severe, and it was gradually replaced at Camp Pike by drafts of men taken from cantonments farther north. Thus the strength slowly declined until November 25, after which it mounted by transfers from other camps to nearly 32,000 at the end of the year.

Polygon of weekly strength of Camp Pike measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the smal rectangle above the polygon.]



CAMP PIKE

CHART NO. 24.

The leading diseases at Camp Pike are given in Table 32.

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The high admission rate of Camp Pike, especially of measles, of its complications, and of primary lobar pneumonia, resulted in a visit by the Surgeon General on December 5, 1917. After citing the alarming figures of admissions to sick report and of deaths, the Surgeon General continues:

> The figures indicate a serious condition of affairs at this camp. The principal cause of measles, as has been pointed out in other camps, is that a large number of the troops come from the sparsely settled States, and have not had measles before.

> Of the 16 cases of meningitis occurring within the month, 10 came from Fort Riley. This is an illustration of the way one camp can infect another by means of cases brought by incoming troops. * * * Crowding in this camp I do not think exists to any appreciable extent. * * * Within the last 15 days 8,000 new men have been introduced into the camp. It is possible that when these 8,000 men begin to show infection, we will go through an epidemic similar to that which we have just passed. However, as most of these men come from the thickly populated State of Iowa, I do not think it probable that they will have measles, as several of the men have just been through the epidemic.
>
> One great difficulty here is lack of segregation. In Camp Bowie, for instance, if we get a case of meningitis in a tent of 9 men, it is a very easy matter to segregate these 9 men and determine whether or not they have been infected here. With a squad-room containing 120 men this is much more difficult.

Measles.—As the table shows, measles appeared in camp in September with 43 cases, rose to 980 in October, and to 1,943 in November; then diminished slightly to 1,288 in December. Practically the entire command was infected. The abatement of the epidemic resulted largely from the exhaustion of susceptible material. An attempt has been made to trace the origin of the measles to the First Arkansas Infantry, which guarded the camp during construction and which had suffered severely from measles. Measles were also prevalent in Little Rock and adjacent territory.

Pneumonia.—As the table shows, primary lobar pneumonia was common and the case mortality high, probably not far from 20 per cent. For lobar pneumonia following measles, the case mortality was over 40 per cent. Primary broncho-pneumonia was fatal in 13 per cent of the cases and broncho-pneumonia following measles in 40 per cent. On account of the crowding of the base hospital by measles, many cases were discharged prematurely and consequently were specially susceptible to pneumonia.

In the pneumonia wards each bed was screened; paper handkerchiefs to be used only once were provided, and the ward was scrubbed daily with an antiseptic solution. There were 54 cases of empyema, complicating pneumonia, with 9 deaths. Many ear complications followed measles. At the base hospital 30 operations were performed for acute mastoiditis.

Scarlet fever.—There was an epidemic of this disease, as many as 196 being in the hospital on December 15. In many cases this was complicated by pneumonia.

Mumps.—An epidemic started in November, with 123 cases. This increased to 344 in December. With the new year the epidemic declined. No deaths occurred, but some cases of orchitis.

Venereal diseases.—The high venereal rate appearing in the statistics is due to old cases found in drafted men. The admission rate for new cases, acquired since connection with camp, is stated to average 3 per 1,000.

Meningitis.—There were 32 cases of this disease and 7 deaths. Of these cases approximately 11 came originally from Camp Funston, with a transfer of troops. The cases occurred spasmodically and there was no area which could be located as a focus of infection. A considerable number of the meningitis cases have followed suppuration of the middle ear, consequent upon infected tonsils. The camp surgeon states that many patients refuse tonsillectomy, some of whom subsequently die of a streptococcic meningitis. He lays stress on the seriousness of the psychological barrier.

16. CAMP TRAVIS, TEX.

Camp Travis lies to the northeast of San Antonio, Tex., a railroad center of about 100,000 inhabitants. The city line includes nearly all the camp buildings. The elevation is 740 feet above sea level. The natural physical conditions and the conveniences of water supply and sewer connections give the location unusual advantages as a site for an Army cantonment.

During November the weather at Camp Travis was dry and warm with 22 clear days and a minimum temperature of 41° on the 20th. In December it was still dry but cooler, a minimum of 19° being reached on the 30th. There were 14 clear days. There was no snowfall in either month and rainfall was far below normal.

To Camp Travis were called from civil life, the following contingents:

	Men.
Sept. 5–10	2,305
Sept. 19–24	1,834
Oct. 3–8	10,000
Oct. 27–Nov. 1	3,666
Total	17,805

These men were from the States of Oklahoma and Texas. The territory included Oklahoma City (65,000), Muskogee (25,000), San Antonio (100,000), Dallas (95,000), Houston (85,000), Fort Worth (75,000), El Paso (50,000), Galveston (40,000), Austin (30,000), Waco (28,000). Taken as a whole the territory from which Camp Travis draws is 23 per cent urban, ranking fourth from the last in order of urbanity.

Polygon of weekly strength of Camp Travis measured by scale on the left.

[Increments are indicated by dotted rectangles of which the unit, 1,000 men, is represented by the small rectangle above the polygon.]

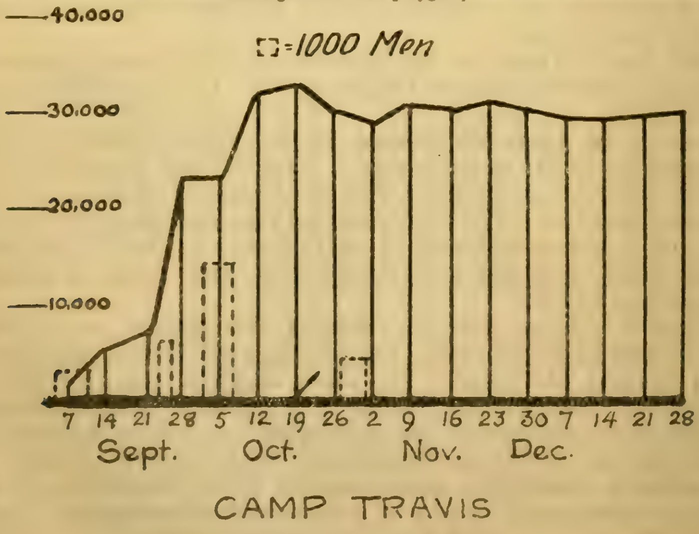

CHART No. 25

The strength of the camp at different dates is shown in Chart 25. After the induction of draft contingents, the population rose to 30,000 and remained nearly constant to the end of the year. This camp had the greatest number of negro troops of any camp in its November to December population, namely, 7,600.

The leading diseases at Camp Travis are given in Table 33.

TABLE No. 33.—*Admissions and deaths, infectious diseases, Camp Travis, 1917.*

Total	483	760	3,892	2,858	4	37	43	84

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

Disease admissions ran high at Camp Travis, as might be expected from the low rate of urbanity of the regions from which the men were drawn and the crowding of the cantonment. Measles totaled 3,813 cases in November and December, after which the epidemic abated.

The division surgeon reports:

> With the first increment sent to this camp by the various local boards were a number of men who were physically unfit to perform the duties of a soldier. These men were naturally more susceptible to disease than were the physically fit. This error was later corrected by sending a board of medical officers from this camp to various parts of the States of Texas and Oklahoma for the purpose of giving instructions to the local boards in the proper method of examination of recruits before sending them to this camp for military service. The beneficial results of this instruction, it is thought, will have its effect in bringing a better class of recruits in the future so far as physical condition is concerned. Many cases of pneumonia followed measles and mumps, particularly the former disease. The cases of pneumonia, as well as influenza, were not localized in the camp but occurred generally throughout the entire camp. The pneumonia epidemic was general throughout the State. Civilian physicians informed me that they had never had so many cases of pneumonia in their practice in previous years.

A special board of medical officers visited Camp Travis on December 27 to consider the epidemic of measles and pneumonia. They decried the failure to differentiate between measles and German measles. A previous attack of one disease does not give immunity to the other. The measles was so widespread that practically all new comers contracted it and the diseases began to die out by the middle of December. As quarantine had become irksome, the board recommended the withdrawal of many of the quarantine restrictions.

The most serious condition the board found was the prevalence of pneumonia. As at other camps there is some uncertainty as to differentiation between lobar pneumonia and broncho-pneumonia and as to the precise number of cases secondary to measles, but it appears that while the majority of cases of pneumonia, and nearly all those of broncho-pneumonia, are related to measles, a considerable amount of pneumonia, this being predominantly lobar, occurs independently of measles. A certain number of cases of pneumonia occurred before the outbreak of measles.

The fatality from pneumonia of all forms during the month was 20 per cent. It is much higher in the pneumonia following measles than in straight lobar pneumonia. While pneumonia is much more likely to be a sequal of true measles, it has been observed in several instances after German measles, but exact figures upon this point are not available as the two forms of measles are not separated.

Infections with the pneumococcus are not limited to the occurrence of pneumonia. There have been many cases of pneumococcal conjunctivitis, five cases of pneumococcal meningitis disassociated from pneumonia, several cases of pleurisy due to this organism without pneumonia and a good deal of the prevailing sore throats and tonsillitis are attributed to the same germ. Pneumococcus infection is, therefore, widely distributed in the camp.

While overcrowding did, according to the recommended standards, not exist in the barracks at the time the board met, the opportunities of close contact were so numerous in the camp that it was suggested that some simple instruction be given to the men as to the risks of such contact and how to avoid them.

As at other camps, measles was a prime factor in the causation of pneumonia, but the continuance and even temporary increase of the pneumonia indicated that this is not the only factor. Other factors to be considered are the dust, not as great here as in some camps, but still considerable when the wind blows, the changing climatic conditions and exposure to cold with thin clothing, although the men were supplied with woolens, overcoats and blankets, and perhaps in some instances, lowered resistance from such causes as hookworm and chronic malaria.

The cerebrospinal meningitis was particularly fatal—24 cases with 10 deaths. There were also several cases of pneumococcus meningitis (without pneumonia). No two cases of meningococcus meningitis have come from a single company and in only one instance have two cases come from a single regiment.

The cases of typhoid were brought in from outside sources. The triple vaccine afforded general immunity.

The number of cases of gonococcus infection admitted to sick report was abnormally augumented at this camp by the induction of 7,500 negro troops.

17. CAMP WADSWORTH, S. C.

Camp Wadsworth is located at Spartansburg, S. C., a railroad junction point of about 20,000 inhabitants. The surrounding region is agricultural.

Swampy ground and poor drainage rendered the camp site unsanitary at first, but this defect was remedied by proper ditching. The disposal of waste presented a problem requiring eternal vigilance, because it was impossible to make a contract with one individual for the removal of manure and garbage. Instead it was necessary to divide the material among the neighboring farmers, most of whom were irregular in hauling away the waste. In poor weather Army transportation had to be provided. Nevertheless, this method of garbage disposal proved satisfactory for the most part, and resulted in a decided conservation of material.

Weather conditions during the last two months of the year were severe at Camp Wadsworth. It was the coldest December and, with one exception, the coldest month recorded for South Carolina. In December the temperature ranged from 70° on the 4th to 1° below zero on the 30th. Rainfall in both months was far below normal. There was recorded one heavy snowfall, 9.5 inches.

At the base hospital there were crowded quarters with practically no bathing or sewage facilities. The unusual cold rendered inadequate the stoves temporarily installed. For several periods of four to five days water connections were frozen and no water was available in wards or mess halls.

The population of Camp Wadsworth consisted of seasoned troops, mainly from the region of New York City. The strength of the camp at different dates is shown in Chart 26. Numbers increased regularly through September, attaining a maximum of 35,000 on October 12. On October 26 the strength stood at 29,000. After November 9 it remained at 30,000 for the remainder of the year.

The leading diseases and consequent deaths at Camp Wadsworth are given in Table 34.

Polygon of weekly strength of Camp Wadsworth measured by scale on the left.

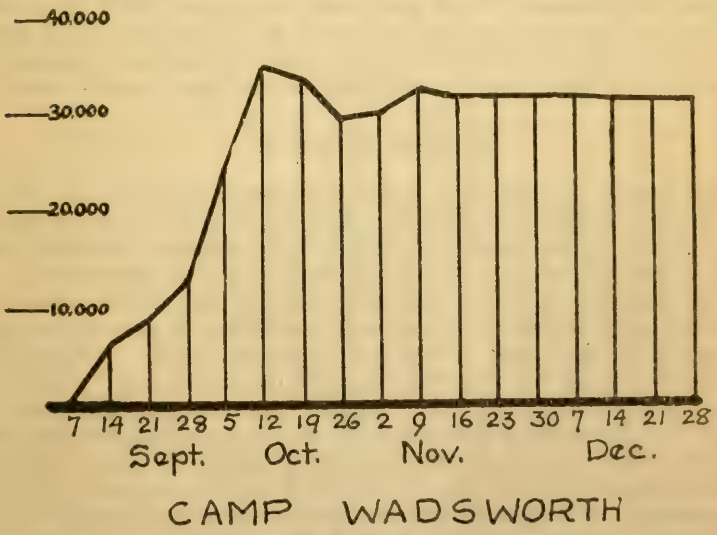

CHART No. 26.

TABLE NO. 34.—*Admissions and deaths, infectious diseases, Camp Wadsworth, 1917.*

Total	134	258	420	250	....	3	2	5

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The effect on the health of the Army of urban origin, with its consequent high degree of immunity from epidemic diseases, is evident from inspection of the figures. Measles, which caused admissions even into the thousands in camp populations drawn from rural regions, appeared only occasionally and totaled only eight cases in four months in an average population of nearly 30,000. German measles caused 88 cases and pneumonia 51 cases during the same period. Venereal diseases ran higher, causing 835 admissions. Nearly all of these cases were contracted prior to arrival at Camp Wadsworth and occurred in regiments that had been on guard duty in scattered detachments, generally so far separated as to prevent proper medical supervision. On November 26 all cases of venereal disease were ordered to the base hospital and kept under guard until cured.

18. CAMP SEVIER, S. C.

Camp Sevier lies about 4 miles northeast of Greenville, S. C., a city of some 20,000 inhabitants. Its entire area contains approximately 1,900 acres, many of which were densely wooded on the arrival of the troops and thickly covered by dense underbrush. The camp is situated on a low flat ridge which runs from northeast to southwest and whose northern and southern slopes afford ample drainage from any part of the troop-covered area. Several brooks and rivulets make the natural drainage most effective.

The temperature was much lower than usual. The year 1917 closed with the coldest December on record and with but one exception the coldest month in the history of South Carolina. The temperature ranged from 78° on the 7th of November to zero on the 30th of December. The precipitation also was exceedingly slight during this period. The moderate snowfall was confined to a period of a few days.

The water supply for the camp is collected in five reservoirs from the watershed on the east side of Paris Mountain. Analysis of the water showed it to be badly contaminated by *Bacilli coli.* The source of contamination is undetermined. The entire water supply is chlorinated by the city of Greenville. Lyster bags were put into operation at the camp and during the period of contamination the water for use of the entire camp was boiled.

The new Thirtieth (old Ninth) Division of the National Guard was assigned to Camp Sevier. This division consisted of seasoned troops from Tennessee, North Carolina, and South Carolina. To these were added, however, considerable increments of drafted men to complete the division. The strength was reported to be about 8,000 on September 7. This number increased consistently at the rate of about 4,000 fortnightly, until November 9, when the strength was 27,000. The camp remained at about this strength during the rest of the year (Chart 27).

Polygon of weekly strength of Camp Sevier measured by scale on the left.

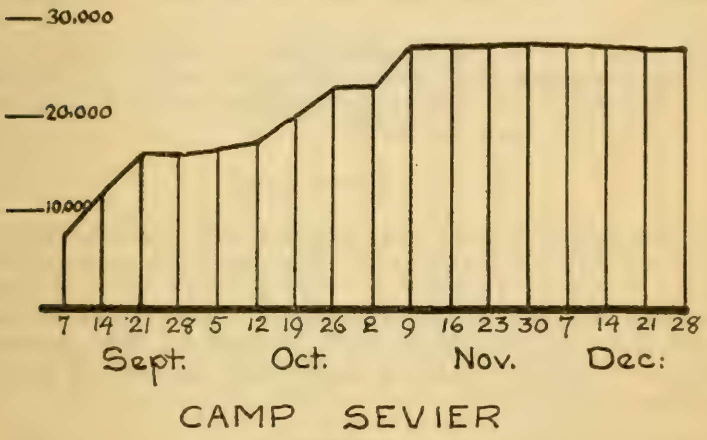

CHART NO. 27.

The leading diseases and causes of death at Camp Sevier are shown in Table No. 35.

Total	396	568	2,919	648	18	100	17	135

---

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The principal epidemic was that of measles, which reached its maximum development in November. Pneumonia, although much less prevalent, reached its maximum frequency during this month. Measles with broncho-pneumonia was the cause of the greatest number of deaths. Broncho-pneumonia claimed 13 and lobar pneumonia 20 deaths. Cerebrospinal meningitis was responsible for 8 deaths.

Venereal diseases were very prevalent and showed the highest frequency in September, soon after the camp opened.

A large number of ear infections followed measles—18 cases of acute mastoiditis were operated upon; 241 salvarsans were given.

The epidemic of measles and pneumonia is accounted for by the arrival of an increment of 9,000 drafted men at a time when there was a sudden drop in the temperature and adequate housing was not available. These men were described as poorly nourished and badly clothed.

The physical condition of all enlisted men of this command showed notable improvement after their arrival in camp. A hookworm survey of the troops was made and an attempt initiated to eradicate hookworm infection from the camp.

19. CAMP HANCOCK, GA.

Camp Hancock is located near Augusta, Ga. As elsewhere, the latter part of 1917 was rather cold, December being recorded as the coldest for 40 years. However, no very great extremes of temperature were reached, the maximum being 70° on the 7th of November and the minimum 11° on the 30th of December. The amount of precipitation was very small. A measureable amount of snow fell in December.

Polygon of weekly strength of Camp Hancock measured by scale on the left.

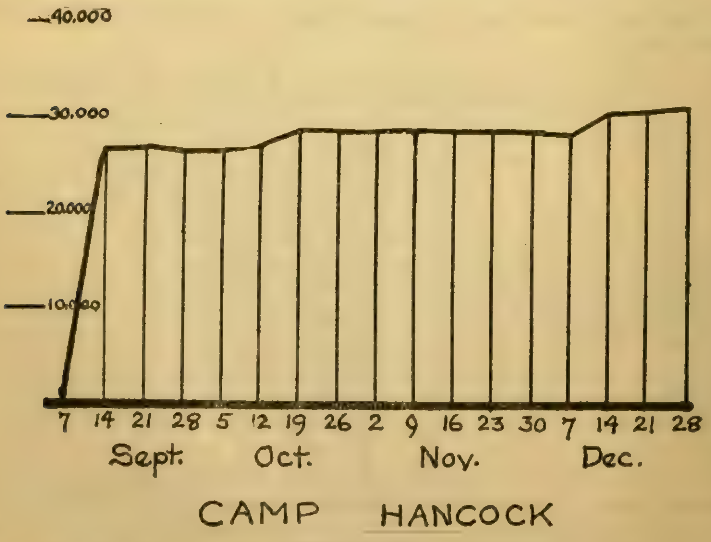

CHART No. 28.

The new Twenty-eighth (old Seventh) Division was assigned to Camp Hancock. This division consisted of seasoned troops coming from the State of Pennsylvania.

The camp early in September reached a strength of 27,000. In October the number was increased to 29,000 and in December to 32,000 (Chart 28).

The leading diseases and causes of death are listed in Table No. 36.

TABLE NO. 36.—*Admissions and deaths, infectious diseases, Camp Hancock, 1917.*

	Admissions.				Deaths.			Total deaths.
	Sept.	Oct.	Nov.	Dec.	Oct.	Nov.	Dec.	
Lobar pneumonia		1	4	8				
Broncho-pneumonia			2	1				
Measles (uncomplicated)			2	8				
Measles and lobar pneumonia								
Measles and broncho-pneumonia								
Measles and other complications								
German measles			4	30				
Mumps		16	17	6				
Scarlet fever	2							
Typhoid fever		2	1	1			1	1
Tuberculosis	1	27	20	19				
Cerebrospinal meningitis		1	1	3	1	1	1	3
Chancroid	2	13	50	24				
Syphilis	8	25	14	25				
Gonorrhea	17	54	139	85				
Total	30	139	254	210	1	1	2	4

The record of disease is unusually small in this camp. No epidemic of any kind occurred. Four deaths only were reported, three of these being due to meningitis and one to typhoid.

The most prevalent by far are the venereal diseases. All others are very infrequent with the exception of tuberculosis.

20. CAMP WHEELER, GA.

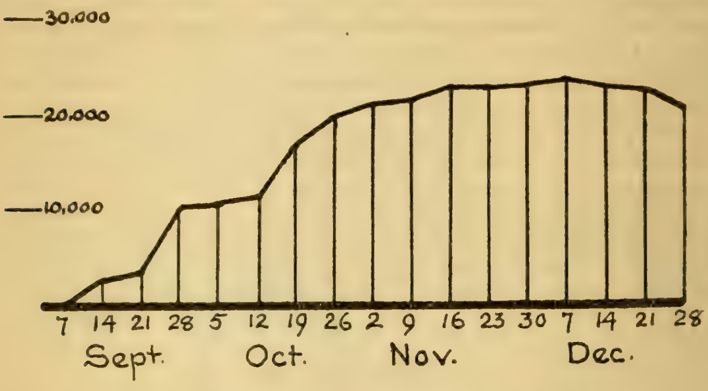
Camp Wheeler is located 5 miles southeast of Macon, Ga., a city of 40,000 inhabitants on the Ocmulgee River. The terrain of the camp consists of broad rolling hills of sandy loam top soil underlaid by clay which hardens readily. One creek flows through the middle of the camp, with two ponds in its course, and another runs south of it. Swamps abounded in and around the camp and these had to be drained. A civil settlement occupied the center of the camp. Altogether the site was not promising.

The water supply is that of Macon. It comes from the Ocmulgee River which is contaminated. The water is filtered and treated with hyperchlorate of lime. The sewage is now disposed of through the trunk sewer of Macon.

The temperature at Camp Wheeler was cool during November; December was the coldest known in Georgia for 40 years. Both months were dry and consequently there was much dust in camp. However, on the 11th to 13th of December sleet and snow fell and did not disappear for 10 days. This cold slush, though it laid the dust, brought another kind of discomfort.

To Camp Wheeler came the National Guard from Alabama, Florida, Georgia, and part of Virginia, a sparsely settled territory. Troops began to arrive in September and by the end of the month there were 10,000, by the end of October 20,000 and by the end of November, 23,000 (Chart 29).

Polygon of weekly strength of Camp Wheeler measured by scale on the left.



CAMP WHEELER

CHART NO. 29.

The leading diseases at Camp Wheeler during 1917 are given in Table No. 37.

The outstanding epidemiological fact in the early history of Camp Wheeler is the outbreak of measles, followed by pneumonia, with many deaths. On the occasion of a personal visit the Surgeon General reported (November 26, 1917):

> There had been a sharp epidemic of measles, some 3,000 cases and, as always occurs with measles, a certain number of cases of pneumonia. At the time of my visit there were some 300 cases of pneumonia in the hospital. While the hospital was crowded,

> the right of way was given the pneumonia cases and they were being well cared for. In the past month there have been about 60 deaths from pneumonia.
>
> I think the reason for the measles affecting so severely this particular camp is the fact that men came from the surrounding Southern States which are sparsely settled and therefore the inhabitants do not, as a rule have measles in childhood. Whatever the original cause of the epidemic and the present conditions, all these evils are accentuated by the crowded condition of the camp. The tendency to pneumonia has no doubt been increased by the fact that the men have generally been exposed to the cold weather of the past month with no other protection than their summer clothing. Clothing is now rapidly coming to the camp and about two-thirds of the men are supplied with woolen garments.

It was recommended that all men in the camp should have 50 feet of floor space each; that no fresh men should be brought into the camp until the epidemic had subsided; that an observation camp should be established and that all men were to be kept under observation until the main camp was free from infection.

The division surgeon offers additional data (Dec. 1, 1917):

> The epidemic of pneumonia in the Thirty-first Division had its true beginning on October 21, six days after the first selective-draft men arrived in camp. Previously there had been a few sporadic cases, never more than 9 at one time. On October 14 there were 3 cases, on October 21, 13; the number gradually increasing until, on November 1, there were 29; on November 10, 68; on November 20, 137; and on November 30, 326 cases.

The etiology of the disease, and the factors favoring its progress are given as follows: physically defective men, 60 to 70 per cent affected by hookworm; inadequate clothing; exposure at drills and even at mess; dust from camp roads, company streets and tent floors; herding in stoveless tents by day and sleeping often two on a small cot in a vain effort to keep warm; an epidemic of measles, brought in chiefly by draft men; an epidemic of bronchitis and other respiratory diseases, with coughing, sneezing, and expectorating in tents, streets and mess halls; and too early return to duty after measles. Of 50 pneumonia cases 12 were returned to the base hospital after having been discharged as cured of measles—3 after 1 day, 1 in 3 days, 2 in 5 days, 4 in 7 days, 1 in two weeks, and 1 in 3 weeks. Of 294 cases returned from the base hospital to the One hundred and twenty-fourth Infantry as cured of measles during the month of November, 30.8 per cent were sent to the hospital with bronchitis or pneumonia.

The rise and decline of measles and pneumonia and the relation of the second to the first are brought out in the following table, which is offered with the warning that it cannot be compared closely with the monthly record in which the admissions are classified somewhat differently.

Admissions.

Date.	Measles.	Lobar pneumonia.	Date.	Measles.	Lobar pneumonia.
Oct. 20, 1917	16	4	Dec. 1, 1917	55	182
Oct. 27, 1917	190	25	Dec 8, 1917	38	81
Nov. 3, 1917	348	24	Dec. 15, 1917	13	56
Nov. 10, 1917	814	28	Dec. 22, 1917	10	51
Nov. 17, 1917	918	52	Dec. 29, 1917	10	46
Nov. 24, 1917	359	128	Jan. 8, 1918	4	35

About 116 cases of pneumonia were preceded by measles, or about 15 per cent of all pneumonias, with a mortality of about 51 per cent. This incidence of lobar pneumonia, secondary to measles, is unique to this camp: for elsewhere the type of pneumonia that is preceded by measles is predominatingly bronchial. It is significant that the regiments largely involved were made up principally of draft men from Florida, new to the service and harboring the hookworm.

Mumps was epidemic from late November until the middle of January. The cases represent about 18 per cent of the command, a fact that would seem to indicate that the epidemic involved nearly all of the susceptible material. About 12 per cent of the cases of mumps developed orchitis. Venereal diseases were abundant; and it is noted that the new cases were chiefly from the newly drafted men.

21. CAMP SHERIDAN, ALA.

Camp Sheridan is located near the city of Montgomery, Ala, Three creeks running from south to north and one from east to west. eventually joining the Alabama River, afforded the natural basis of a drainage system. It was necessary to widen and deepen all of these creeks and to connect them with artificial drainage ditches. These drainage canals, both natural and artificial, became filled and clogged after every rain and necessitated a repetition of the original procedure of cleaning these channels. The soil is alluvial in nature and pulverized very quickly under traffic, resulting in a great deal of dust in dry weather.

The climate was extraordinarily pleasant barring a considerable drop in the temperature. The temperature varied from 75° on November 7 to 15° on December 9. There was slightly less precipitation than usual and practically no snowfall.

The water supply is excellent, and is piped from the city of Montgomery. It is soft and comes from artesian wells. A few instances of colon pollution were reported at first but are attributable to the dirt entering the mains during the process of laying the pipe. Some difficulty is experienced in obtaining sufficient pressure.

The garbage was at first disposed of by using a modified Guthrie incinerator, but this proved an expensive and inexpedient process because of the high price and difficulty in securing an adequate supply of fuel. The system now in force is the collection of liquid garbage by means of pump wagons. The liquid garbage is dumped two miles below the camp into a nearby stream emptying eventually into the Alabama River. The solid garbage is sold to a hog-feeding company.

The new Thirty-seventh (old Sixteenth) Division was assigned to Camp Sheridan. This division consisted almost wholly of seasoned troops from the State of Ohio. There were a few from West Virginia and Alabama also. The later increments of drafted men were principally from the Southern States.

Camp Sheridan reached its maximum strength of 24,000 early in October. This number was fairly constant throughout th period. It was decreased by about 1,000 late in December (Chart 30)

The leading diseases and causes of death for Camp Sheridan ar shown in Table No. 38.

Polygon of weekly strength of Camp Sheridan measured by scale on the left.

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The disease record of this camp is unusually small; no serious epidemics of any kind occurred. Four deaths only were reported, two from meningitis and one each from lobar pneumonia and measles complicated by broncho-pneumonia.

Venereal diseases are by far the most frequent. The relatively high percentage of venereal diseases is explained in part by the fact that more than three regiments of this division before coming into camp were distributed on guard duty in small detachments through the State of Ohio near the larger cities and towns. An effort has been made with some success to educate the troops as to the significance of these diseases.

22. CAMP McCLELLAN, ALA.

Camp McClellan is situated about midway between Anniston and Jacksonville, Ala., and has the advantage of natural surface drainage, practically every organization being on a small creek. The soil of the camp is a mixture of clay and some gravel, which becomes very muddy in wet weather and very dusty in dry weather.

The temperature of the last three months of the year was below the average, varying from 74° above zero on the 8th of November to 8° above zero on the 30th of December. In both November and December the amount of precipitation was below normal. There was practically no snowfall in either of these months. There were 18 clear days in November and 15 in December.

Camp McClellan is amply supplied with excellent water from a spring, the source of which is Blue Mountains. The capacity of the spring is 33,000,000 gallons in 24 hours.

There was no system of sewage at first and 90 per cent of the latrines took seepage water and required pumping. Latrine pits on side hills, unused by troops, would frequently fill to within a foot or two of the top, necessitating pumping. Five excavating tanks have hauled on an average 12,500 gallons of polluted seepage water per day. Improvised crematories were constructed and the five in operation at the end of the year are capable of disposing of from four to five thousand gallons of sewage each, per day. Also a system of sewage was installed at the base hospital.

The new Twenty-ninth (old Eighth) Division of the National Guard was assigned to Camp McClellan. This division was composed of seasoned troops from the States of New Jersey, Virginia, Maryland, Delaware, and the District of Columbia. The percentage of urbanity is high in these States.

During the last three months of the year 1917 the strength of the camp remained fairly constant. From the first increment of 14,000 in September the number increased to about 25,000 in October and 27,000 in November and December (Chart 31).

Polygon of weekly strength of Camp McClellan measured by scale on the left.

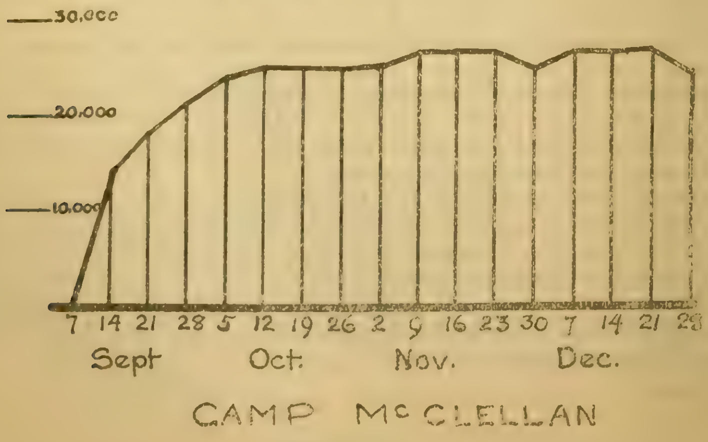

CHART No. 31.

The leading diseases and consequent deaths at Camp McClellan are shown in Table No. 39.

TABLE NO. 39.—*Admissions and deaths, infectious diseases, Camp McClellan, 1917.*

	Admissions.				Deaths.			Total deaths.
	Sept.	Oct.	Nov.	Dec.	Oct.	Nov.	Dec.

Chancroid	12	29	22	15				
Syphilis	6	23	40	23				
Gonorrhea	62	190	85	61				
Total	113	337	290	318	1	2	1	4

It is noticeable that in this camp, containing seasoned troops, no serious epidemics occurred. Venereal cases ran rather high, 568 cases being treated during this period. Two hundred and fifteen uncomplicated cases of measles with no deaths were reported. In 125 instances pulmonary tuberculosis was assigned as the reason for disability-discharge from the division. One death occurred among the 45 cases of lobar pneumonia. Three other deaths occurred, one each resulting from cerebrospinal meningitis, measles with broncho-pneumonia, and typhoid fever, respectively.

Ten cases of typhoid fever occurred during this period and all cases were confined to the Fifth New Jersey Infantry, who apparently brought the disease with them. Examination of their service records showed that in practically every case the typhoid inoculation had not been completed. Sixteen cases of malaria were also reported as having been brought into the camp from outside sources.

Eight cases of meningitis were treated during October, November, and December. Seventy-three carriers were detected during this same period. Of the 413 examined in October 1.6 per cent were carriers; of the 539 examined in November 5.2 per cent were carriers. The percentage of carriers was still further increased in December, when 7.3 per cent of the 502 men examined were reported as carriers. Great care was exercised in segregating and isolating all carriers detected.

23. CAMP SHELBY, MISS.

Camp Shelby is located 11 miles southeast of Hattiesburg, Miss., on a rather high, rolling plateau, covered with pine forests, once cut over. The soil is of clay, covered with a light coating of fine sand, which dries very quickly on the surface, but which is only slightly impervious. The natural drainage is good, as the general surface of the area is marked by many ravines.

The temperature during this period was unusually low for this region, varying from 75° on November 7 to 1° below zero on December 30. There was very much less rainfall than usual. There was considerable snowfall in December, but for the most part confined to a very few days.

The permanent supply of water is from three wells over 300 feet deep, passing through several impervious layers of clay and filtering layers of sand and gravel. The disposal of waste proved a real problem. The impervious character of the soil precluded any chance of absorption. This necessitated the use of odorless excavators for pumping out the waste. The kitchen garbage was disposed of to a contractor. Some difficulty was experienced in incinerating the manure and this was later disposed of to contractors for fertilizer.

Work began on the camp July 22, 1917, and the new Thirty-eighth (old Seventeenth) Division began its organization August 25 with the arrival of the commanding general and the division staff. This division was composed of seasoned troops from the States of Indiana and Kentucky. To these were added a considerable number of drafted men from civil life to complete the organization.

This camp reached its maximum strength very slowly by small increments. It started with about 2,000 men in September and only reached its maximum strength of 30,000 in November. In December this strength was decreased to about 27,000 (Chart 32).

The principal diseases and consequent deaths for Camp Shelby are listed in Table No. 40.

TABLE No. 40.—*Admissions and deaths, infectious diseases. Camp Shelby, 1917.*

	Admissions.				Deaths.			Total deaths.
	Sept.	Oct.	Nov.	Dec.	Oct.	Nov.	Dec.	
Lobar pneumonia	4	33	42	46		2	7	9

Total	53	518	1,797	869	1	27	22	50

As usual, measles and mumps far outnumber the other diseases in frequency, but neither reached the proportions here that prevailed in many camps. Measles was reported from the very first, being brought in by the troops from Kentucky. It did not reach any disturbing proportion until the last of October, when the larger increments of drafted men furnished material for the spread of the disease. The crests of the waves of incidence occurred on the 8th and 22d of November. After the 3d of December the number of admissions for measles began to fall off rapidly and by the last of this month the epidemic was over.

Polygon of weekly strength of Camp Shelby measured by scale on the left.

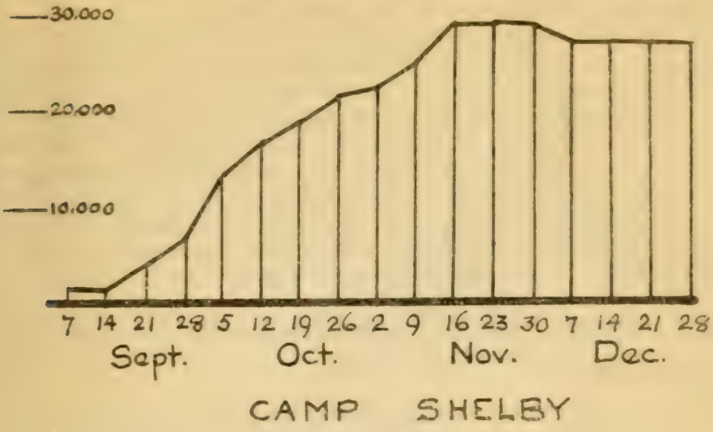

CHART NO. 32.

The most frequent cause of death was measles complicated with lobar and broncho pneumonia. Thirty-one deaths were so caused. Although some difficulty was experienced in housing all the patients during the height of the epidemic the camp surgeons feel confident that none of the deaths or complications could well be attributed to exposure.

Primary broncho-pneumonia resulted in three deaths and lobar pneumonia in nine deaths during this period. Two deaths occurred from meningitis in November and three in December. The first meningitis cases to appear were confined to one regiment, but all the later admissions were single isolated cases in different organizations.

Venereal diseases were not as frequent in this camp as in some nearby. As usual the times of greatest frequency correspond to the time of arrival of considerable increments.

Hookworm infection was studied in the Kentucky troops. In one regiment coming from the eastern part of Kentucky the proportion of positive cases was found to be 17.4 per cent. In some of the companies the proportion ranged as high as 30 per cent. Another regiment drawn from central and western Kentucky showed only 7 per cent of positive cases.

The officers of the Public Health Service, on duty in Hattiesburg, rendered valuable assistance in the control of preventable diseases, in antimalaria work, in the supervision of restaurants, milk and food supply, and in reporting the occurrence of communicable diseases among the civilian population.

24. CAMP BEAUREGARD, LA.

Camp Beauregard is located about 6 miles north of Alexandria, La., a city of 15,000 inhabitants, situated on the Red River. The camp is built on fairly rolling ground, making the drainage a comparatively simple problem. There were, however, a number of swamps in the extra cantonment area which had to be drained or oiled, under the direction of the United States Health Service. The terrain is commonly known as "cut-over pine-tree land," but some of the pine was left standing.

The water supply is derived from five artesian wells, furnishing about 850,000 gallons per day of good quality.

To Camp Beauregard came first the National Guard of the States of Arkansas, Louisiana, and Mississippi, States characterized by few large cities (compare the list given under Camp Pike, page 83), and an urbanity near the lowest of any camp. Subsequently increments were received of drafted men. The strength of the camp at different dates is shown in Chart 33. It gradually increased from about 1,000 to 5,000 during September to 7,000 during October, rapidly to 23,000 during November, in which month 9,000 drafted men were received from Camp Pike, and remained at about this strength during the rest of the year. There were no colored troops.

Polygon of weekly strength of Camp Beauregard measured by scale on the left.

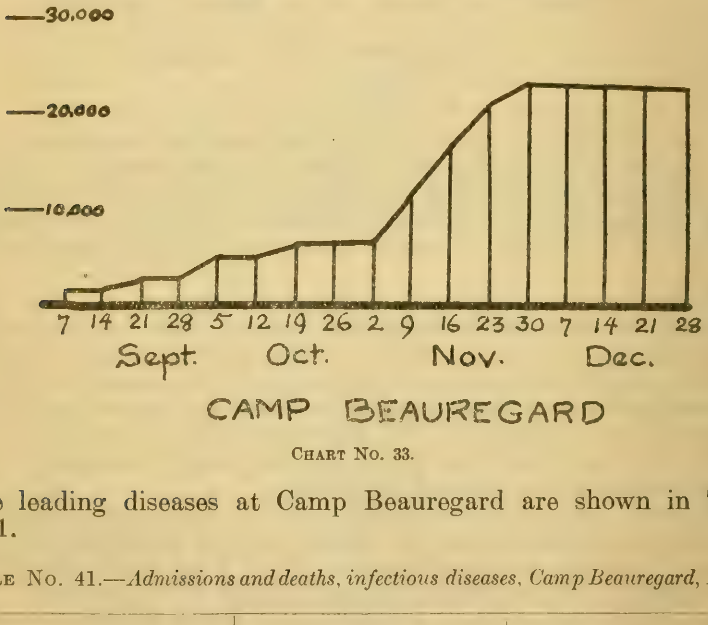

CHART No. 33.

The leading diseases at Camp Beauregard are shown in Table No. 41.

Total	37	272	2,481	1,782	1	73	42	11

The division surgeon calls attention to the fact that there was a marked increase in the sick rate after the arrival of the drafted men. A large percentage of these men came from small towns and rural districts, and had not yet learned the principles of "taking care of themselves," especially in the open. Many of these men had never had the usual diseases of childhood, and it would seem that their environments and previous habits of life had rendered them especially susceptible to communicable diseases.

This table shows that measles reached epidemic proportions in November. The peak of incidence was reached November 19 to 22. The epidemic declined greatly in December and ceased completely with the close of the year. The epidemic of measles was accompanied by pneumonia, especially broncho-pneumonia, and many deaths occurred in November. The first admission for pneumonia occurred one week after the maximum incidence of measles was reached.

The base hospital not being fully constructed or prepared to care for such a large number of cases, field hospitals were operated for this purpose and, later, regimental isolation camps were established for the milder cases.

The precautionary measures taken by division orders to prevent the spread of this disease were as follows: prompt recognition of all early cases by inspection twice daily of all enlisted men and isolation of cases in hospital or isolation camps; furling of tents from sunrise to sunset, weather permitting; opening of tent ventilators and tying back of tent doors at night; fires were extinguished at taps; additional tentage to reduce the number of men per tent from eight-plus to six-plus, and the arranging of cots so men would sleep head to foot; men from different organizations were not allowed to congregate in exchanges, Y. M. C. A. buildings, or other places.

Cerebrospinal meningitis.—The number of cases of this disease during 1917 at Camp Beauregard was 50. There were 16 deaths, giving a mortality of 32 per cent. The distribution of cases to January 9 was as follows:[1]

Nov. 9–16	3
Nov. 17–19	3
Nov. 25–30	5
Dec. 2–4	3
Dec. 7–13	3
Dec. 15–20	5
Dec. 21–28	7
Dec. 28–Jan. 3	28
Jan. 4–9	17

It will be noted that there was a general increase in increments throughout December, with an explosion during the week ending January 3. During the week following there was a decrease of 11 cases, evidently resulting from restrictive measures enforced on January 3. The occurrence of cases was widespread, and there was only one instance where men from the same tent contracted the disease. Thirty-seven of the total number of cases came from the One hundred and fifty-sixth Infantry. This regiment received nearly 2,500 drafted men from Camp Pike. These men were however, kept in quarantine for about a month before being fed into the regiment, and a good number of cases occurred while these men were in quarantine. This would seem to indicate that the drafted men were more liable to meningitis than the National Guard troops.

---

[1] The distribution of cases by months in this table does not agree exactly with Table 41. This is due to the fact that some cases in the last table were reported later than in Table 41.

The number of fulminating cases in which death occurred within twelve hours after onset of symptoms was two. All cases were treated with serum. There has been nothing new developed in the diagnosis or treatment of this disease. Best results have followed the use of serum obtained from the New York State Board of Health. The diagnosis in all cases was confirmed by spinal fluid findings. Measures to prevent the spread of this disease have been as follows: isolation of all cases; isolation and examination for carriers of all contacts; early in the epidemic all organizations in which cases occurred were quarantined as a whole; this was later modified to the systematic examination for carriers in ever widening circles, starting from the case.

On account of lack of laboratory facilities at the base hospital and its distance from the camp, the examination for carriers was done in the laboratory cars of the Louisiana State Board of Health, which were generously put at the service of the division surgeon by its president.

These cars were placed on a siding centrally located to the whole division. The work was done by the director of the laboratory cars and officers from the laboratory of the base hospital.

Isolation camps for carriers, surrounded by barbed wire and under guard, were established at three points. Carriers and contacts were treated there until three negative cultures at intervals of three to six days were obtained. The number of cases examined was 7,754; the number of carriers found was 250; the number of carriers developing the disease was one.

As the table shows, mumps became epidemic in November and increased greatly in December. There were about 1,800 cases by the end of the year. Two field hospitals were established as mumps hospitals, and the overflow taken care of in mumps camps, which were established in the rear of organizations. These mumps camps were used more especially for the uncompleted type of cases. Most of the cases were of a mild type, the usual complications being orchitis; two cases were noted with mild miningeal symptoms, with negative spinal-fluid findings. It is impossible to account for these symptoms. The majority of the cases showed no complications and performed light duty. There were 2,063 cases up to January 13, 1918, and it was expected that in a short time all the susceptible material would be used up.

The conditions of disease from measles, pneumonia, and meningitis, led to a personal visit to and report concerning conditions at this camp by the Surgeon General, December 1, who concluded that the epidemic was largely due to crowding and urged that each man should receive 50 feet of floor space in the tents instead of the 28 feet which they had previously occupied. He noted that the men had largely come to camp in their summer clothing and on account of delay in supplying them with winter underclothing they had suffered some discomfort and been rendered more liable to pneumonia.

25. CAMP DONIPHAN, OKLA.

Camp Doniphan is located on the reservation of Fort Sill, a rolling, grassy country, with small streams at varying intervals, at an altitude of 900 to 1,000 feet above sea level.

The temperature at Camp Doniphan was changeable in October. A hard freeze occurred on the 19th, and on the 30th the temperature fell to 15° F. Again, in November the thermometer stood at 9° on the 30th and close to zero on the 6th of December. Meantime it was exceedingly dry. A peculiar feature of the climate of Camp Doniphan is the frequency of windstorms. These storms invariably carry thick clouds of dust of such intensity that it is often difficult to see an approaching vehicle a short distance away. They last from 12 to 24 hours and carry dust, according to aerial observers, to a height of 3,000 feet.

Water for Camp Doniphan comes from Lake Lawtonka, a reservoir 7 miles distant. Some colon bacilli were found at first, and hypochlorite of lime was used in all drinking water; later the colon bacilli disappeared, and the water was treated with chlorine at the lake. The sewage system of the plant was not installed until late in the year.

To Camp Doniphan came first the National Guard of the States of Missouri and Kansas (see Chart 34). Only about 3,000 came in at the beginning, but on the 25th of September other troops arrived and continued until October 15, 1917, when the last unit came in. On October 20, 3,000 drafted men arrived, making a total in the division at that time of over 24,000. The troops came with cotton clothing, woolen clothing not having been issued until considerable severe weather had been experienced; and, to add to the difficulty of the situation, the weather for November and December was unusually severe.

The troops were quartered in the large pyramidal tents, 9 to each tent, and a number of organizations had 12 to a tent. Sibley stoves were used for heating.

Polygon of weekly strength of Camp Doniphan measured by scale on the left.

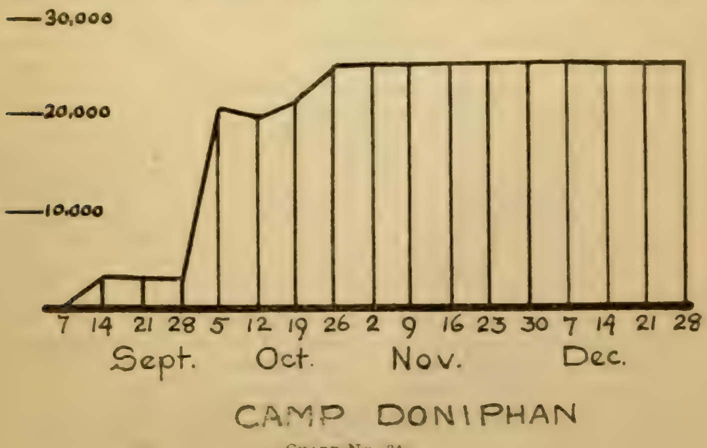

CHART No. 34.

The frequency of the principal contagious diseases and deaths is shown in Table 42.

TABLE NO. 42.—*Admissions and deaths, infectious diseases, Camp Doniphan, 1917.*

Gonorrhea	20	329	138	68				
Total	49	489	581	1,222	2	21	14	37

The most striking feature of Table 42 is the large number of cases of measles with relatively few cases of pneumonia as complications. The camp surgeon reports as follows:

On October 12, 1917, Company H, One hundred and thirty-ninth Infantry, arrived in camp. This company had been detained at Abilene, Kans., for some weeks on account of measles, and after having undergone a period of quarantine of 18 days at that place, had been permitted to come to this camp. However, upon arrival at this camp a case of measles was discovered. It was isolated immediately and the company again put in quarantine in this camp. Cases occurred from time to time in this company until almost every man had suffered an attack. This infection was peculiar in that it was mild, attended with few complications, and in that the attack lasted only a few days. A number of men suffered two and several three attacks of this infection. Maj. Sidney Straus, Medical Reserve Corps, chief of the medical section, base hospital, makes the following comments on this infection: "We have treated in the contagious wards of the base hospital, Camp Doniphan, Fort Sill, Okla., some 20 odd cases from Company H, Third Kansas Regiment, now the One hundred and thirty-ninth Infantry, the exact diagnosis of which is doubtful. None of the patients have been at all sick. There has been no lachrymation or photophobia, and but few sore throats. The temperatures have been normal or very slightly above normal. A few show a typical exanthem on hard palate, consisting of pea-sized irregular pinkish macules, discrete in every instance. A few cases show typical Koplik spots. Many show a small punctate eruption just at the junction of the hard and soft palate, of the nature of petechiæ. There were occasionally a few petechiæ on the mucous membrane of the cheeks. The eruption consisted of small discrete dark red macules, scattered mainly over chest and abdomen, disappearing very rapidly in two or three days. The contagiousness of the disease and character of the exanthem lead one to believe that we are dealing with a very mild epidemic of measles." This company was kept in quarantine until December 4, 1917, when, 18 days having elapsed since the last case, they were released and allowed to proceed to their regimental area. In the meantime cases had developed in several other regiments in the division. Careful instructions were issued to regimental and other independent unit surgeons on the following points: Sending of case to hospital at once; isolation of contacts; examination of contacts twice daily; careful examination of all cases at sick call for suspects; establishing of a camp for suspect cases in each regiment or other unit and placing of guard around same.

However, in spite of these measures there was a gradual and continuous spread of the infection. On December 3 a memorandum was issued to the entire command. The high-water mark was reached on December 24, there being on that date 486 cases. From this date there was a gradual falling off, so that on December 31 there were only 356 cases.

The proper handling of the epidemic was interfered with by delay in finishing the base hospital, which was not completely ready for occupancy by the end of the year. The post hospital that had to be used in the emergency epidemic proved wholly inadequate for this purpose.

Lobar pneumonia (primary) assumed a threatening aspect in November with 76 admissions; it continued through the winter, causing many deaths.

Meningitis.—On November 7, 1917, a case of meningitis developed in Caisson Company No. 2, One hundred and tenth Ammunition Train. The company had just arrived and was mobilized at this place, being made up of National Guardsmen from Kansas and Missouri. The man was sent to the base hospital at once and all tentmates cultured. On November 8 another case developed in an adjoining company. Similar methods were pursued in this instance, and the carriers treated with a spray of dicjoloramine-T. From these cases there was a gradual spread to other organizations, so that on December 31 there were 18 cases.

Isolation camp.—On December 11 the Surgeon General visited the camp and made an inspection of the base hospital and the camp. As a result of the Surgeon General's recommendations two important sanitary measures were put into effect a short time afterwards—the reduction of the number of men to 5 per cent and the establishing of the isolation camp. This camp was established about one-half mile northwest of division headquarters, put in command of a medical officer, and sufficient tentage furnished from the outset to accommodate all contacts, with only five men to the tent. All contacts were sent immediately for the following: measles, cerebrospinal meningitis, scarlet fever, diphtheria, and, at the outset, a few for mumps. The principle followed was to quarantine in units of five. The camp had been in operation only 15 days on December 31, the last day of this report, but the effectiveness of this plan had already become manifest, even at that date.

26. CAMP MAC ARTHUR, TEX.

This camp at Waco, Tex., received the Thirty-second (old Eleventh) Division, consisting mostly of National Guard troops from Michigan and Wisconsin.

The weather at Camp MacArthur was unusually cold during the months of November and December and reached 30° on the 17th of the latter month. The season was exceptionally dry.

To Camp MacArthur came troops as shown in Figure 35. The strength of the camp reached a maximum of 26,000 in October, and thereafter diminished slightly.

The leading causes of admission to sick report and of death are given in Table 43.

TABLE NO. 43.—*Admissions and deaths, infectious diseases, Camp MacArthur, 1917.*

	Admissions.[1]				Deaths.			Total deaths.
	Sept.	Oct.	Nov.	Dec.	Oct.	Nov.	Dec.

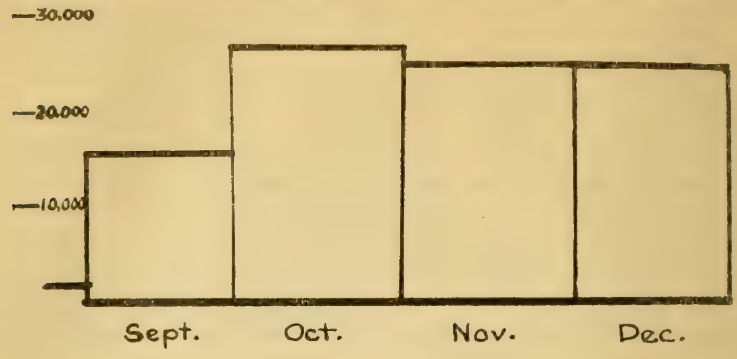
Polygon of weekly strength of Camp MacArthur measured by scale on the left.



CAMP MACARTHUR

CHART No. 35.

There were many cases of measles, but these resulted in exceedingly few complications and only one death. There were also numerous admissions on account of tuberculosis and lobar pneumonia, but the fatality was very small.

27. CAMP LOGAN, TEX.

This camp is located at Houston, Tex., at a point less than a mile west of the corporation limits of that city, a railroad and cotton center of 100,000 inhabitants. The camp site has the shape of a blunt-ended triangle, the apex lying in an easterly direction and toward the city of Houston, at an elevation of 50 feet above sea level, and contains 2,000 acres. The terrain, although close to the Buffalo River, is practically on a dead level, and it has been necessary to dig ditches, 6 to 7 feet deep for mains with sufficient laterals, in the vicinity of the occupied areas to provide rapid drainage for bath and surface water. Conditions have been much improved since the camp has been established, until at the present time there is no difficulty in securing the prompt drainage of all surface water within 24 hours after rainfall.

The water supply is derived from an artesian well which has a depth of 557 feet and a capacity of 1,000 gallons per minute. The camp reservoir has a capacity of 1,600,000 gallons and is roofed, so as to prevent contamination and the growth of algæ. The weather during the last three months of the year was exceedingly dry, and even near the Gulf coast exceptionally cool, though the minimum temperature for December was only 20° F.

To Camp Logan was sent the old Twelfth Division of the National Guard from the State of Illinois. These were mostly seasoned men, largely of urban origin. Figure 36 shows the weekly changes in strength and indicates that transfers occurred from and to the camp, which reached its maximum strength of 33,000 in November.

The number of admissions to sick report and deaths from principal diseases are given in Table 44.

Measles and German measles, while common, never assumed epidemic proportions. Infected squads were isolated and their bedding insolated daily for 12 days.

Polygon of weekly strength of Camp Logan measured by scale on the left.

Total	54	370	628	787	1	3	7	11

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

Venereal disease.—A large majority of these cases were imported into the camp and consisted of old chronic cases that were overlooked or waived by the examining officers. This and the fact that regimental surgeons were required to card all cases of venereal diseases for record will account for the high venereal rate for this disease. It was the fact that many of the organizations were without the facilities for prophylaxis at mobilization camps.

Typhoid fever.—All cases are believed to have been contracted before joining the division, as all of these men had had their first inoculation.

28. CAMP BOWIE, TEX.

Camp Bowie is located in the suburbs of Fort Worth, Tex., on a high dry rolling and generally fine terrain, but a little too much intermingled with a suburban residential district.

The weather during the last months of the year was unprecedentedly dry, which was the cause of much dust in camp. November was of average temperature until toward the end severe and frequent "northers" set in. December was cold, the temperature being 12° on the 10th of the month.

The first contingent of troops belonging to the Texas and Oklahoma National Guard arrived in camp August 25. At this time temporary barracks were partly constructed and latrines established, but no kitchen incinerators had been made. The base hospital had not been started, and the sick were kept in tents. By September 28, 17,000 troops had arrived and this camp gradually increased, by adding drafted men from Camp Travis (of inferior physique), up to 28,000 by November 23. These were mostly National Guard troops from Texas and Oklahoma, States without large cities, except San Antonio and Dallas (each about 20,000), Houston (100,000), El Paso (about 50,000), Galveston (35,000), and Oklahoma City (10,000). The population of the area is prevailingly rural (Chart 37).

The frequency of the leading infectious diseases at Camp Bowie was as follows:

Table No. 45.—*Admissions and deaths, infectious diseases, Camp Bowie, 1917.*

	Admissions.[1]				Deaths.			Total deaths.

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

Polygon of weekly strength of Camp Bowie measured by scale on the left.

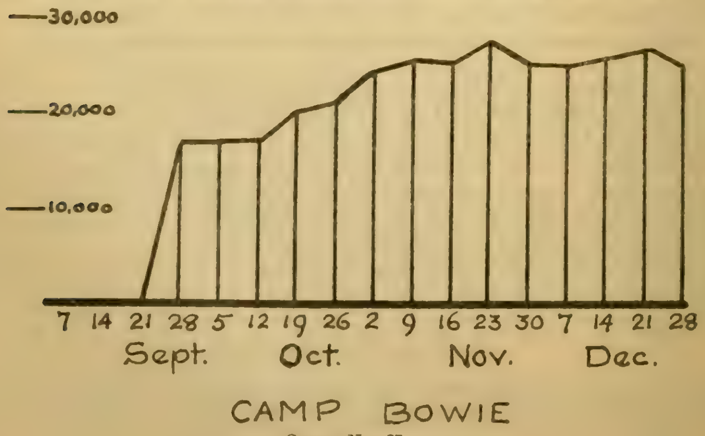

Chart No. 37.

The most striking feature of this table is the large number of cases of measles accompanied or followed by much lobar pneumonia and some broncho-pneumonia. There were six deaths from cerebrospinal neningitis. The base hospital reports concerning this epidemic as ollows:

> The first case of measles occurred the latter part of August was promptly isolated nd the necessary precautions taken by examination of contacts for early signs. An ccasional case of measles developed through September and during October. An ndeavor was made to control the spread of this disease, but owing to the fact that new ontingents of troops were arriving daily, new recruits coming in at all times, and the act that a detention camp had not been established, the cases still continued to levelop in different parts of the division. Many of the surgeons were inexperienced n Army work and did not appreciate the necessity of prompt isolation.
>
> Many of the cases of measles were very mild and some of them were never seen by he regimental surgeons, being discovered in many cases by accident and sent to solation after the spread of contagion had been effected. There were ample instrucions issued to all surgeons for inspection of all troops twice daily, in order to detect he very earliest signs. In many cases Koplic spots did not appear or were not disovered. A great many of the cases were so mild that they were undoubtedly cases of otheln and were practically well before it was realized that they had been infected, ome of them being considered by the regimental surgeons as ordinary colds.
>
> About October 20 an epidemic of measles broke out in the camp, and by the end f the first week in November every ward in the hospital had been filled. Then the varehouses, laundry, chapel, and guardhouse were used to house patients, and tents rom the field hospitals of the division were called into use. The maximum number f patients in the hospital on any one day occurred on November 22, when the morning eport showed a total of 1,887 patients in the hospital. The incoming movement of atients at this time was very rapid, some days there being admissions of more than 300 patients per day. Telegraphic request for hospital beds and clothing was made rom time to time, and these requests were filled as promptly as transportation faciliies permitted. Patients coming to hospitals were required to bring with them their ots and blankets, and quilts and comforters were furnished in large numbers by the Red Cross Association. By means of these measures the hospital was able to provide easonably adequate accommodations for all the patients. The sick were transferred to the wards which were equipped with proper hospital furniture and where members f the Army Nurse Corps and the more experienced of the enlisted personnel were n duty.
>
> By the end of the month of December the number of daily admissions to the hospital had decreased so that there remained only 550 patients in the hospital at the nd of the year.

The Surgeon General of the Army visited this camp and reported to Chief of Staff on December 3, 1917, in part, as follows:

> We have had in this camp during the past month 45 deaths from pneumonia, with 38 cases admitted. There have been about 2,900 cases of measles in the same length f time. The causes of this condition are much the same as in the other camps reorted upon. The great number of cases of measles is due to the fact that the men come rom the sparsely settled States of Texas and Oklahoma and have not had measles in hildhood; but the largest cause is due to the overcrowding of the camp. We have at resent nine men to a tent. I recommend that the division commander be directed o furnish sufficient accommodations, so that each man will be allowed 50 feet of floor pace. This would give not more than five men to a tent.
>
> Measles and other epidemic diseases are introduced into these camps by cases being rought by the incoming troops. To provide against this, an observation camp should e established where all newcomers should be kept under observation for at least 14 ays, and no new men should be placed in general camp until it is free from infection. recommend that the division commander be directed to establish such observation amp; that no fresh men be sent in until he is ready to receive them under the above nstructions.
>
> The base hospital is in an unfurnished condition: no water in the hospital, no plumbng or sewer connection. With the large number of patients in this institution, this ck of water, plumbing, and sewer connection causes serious inconveniences to the ick and increases greatly the burden of caring for them.

An epidemological board visited the camp on December 31 and reported as follows:

Venereal disease.—As in other camps the venereal rate is unduly high because men were enlisted with venereal disease. Of 450 cases counted, 239 contracted their disease prior to entry into the service.

Measles.—The morbidity from measles has been very large in this camp and the morbidity and mortality from pneumonia has doubtless been greatly increased thereby. * * * The division surgeon reports that there were a few cases of measles on August 30 and that a few cases developed in September. These cases were all mild. It is to be noted that no differentiation or separation of measles and German measles was made nor seriously attempted. We can not, therefore, know what proportion of each disease was represented by the figures. General experience of the fact that German measles is less common in civil life than the ordinary average, together with the experience at Camp Cody where separation of the disease showed 89 per cent of German measles, leads us to think that there was probably more susceptible material for that disease to act upon, but cross infections were undoubtedly so numerous that it is quite impossible to make sound estimations as to the prevalence of the two diseases. We may say, however, that exposure to each was probably general throughout camp and in each instance until it had used up practically all susceptible material, after which it subsided. That the epidemic is burned out until an influx of new men produces new material for the disease appears to be shown by the fact that only four new cases have appeared since December 21. That cross infection in hospital followed by incubation produces, and early symptoms in camp tend to contribute to, the more rapid using up of the more susceptible material, to the quick development of a large epidemic, we have no doubt.

The striking difference of incidence in the One hundred and forty-third Infantry (817 cases of measles) and the One hundred and thirty-second Field Artillery (87 cases of measles) led us to make some inquiries as to the places of recruitment of these regiments. This inquiry brought out the fact that 29 militia companies that had contributed to the One hundred and forty-third Infantry came from 25 towns, of which all but a few towns were very small, and that the men were mostly country men from sparsely settled regions. On the other hand, the Cavalry troops which had been transferred into the One hundred and thirty-second Field Artillery all came from cities and the companies were reported to be composed mostly of men from the cities, with the exception of the headquarters company from Taylor, Tex., said to be composed mostly of country men. Of course, most city dwellers have had measles in childhood.[1] That all city and country men have not had a similar childhood experience has been a misfortune to this camp and to the military service.

A study of 102 cases of pneumonia (63 lobar and 39 broncho-pneumonia) was made in December by Drs. Jobling and Dorcher, with the following results:

		Per cent.
Total type determinations	62	
Total type 1	22	36.
Total type 2	0	0.
Total type 2, atypical	9	15.
Total type 3	2	3.
Total type 4	29	47.
Total number hemolytic streptococcus	31	
Streptococcus from lungs at autopsy	18	
Streptococcus from pleural fluid	113	
Total autopsies	30	
Lobar pneumonia	3	
Broncho-pneumonia	27	

Many of the cases of pneumonia were accompanied by a streptococcic infection an rapidly developed a very virulent empyema, which was found in most of the case that died. Believing that in many cases the streptococci came from bad teeth, th dental surgeons started a survey and extracted all roots, starting the correction o diseased teeth.

The meningitis epidemic started with the first case in October. This case died October 22. There were no further cases until th week ending November 24, when five cases were reported. All con tacts of meningitis were isolated and examined for carriers, the carriers being isolated in the base hospital and treated until free from infection. Later, when the laboratory force could get the time, the entire company was swabbed and plated to detect carriers in each company in which a positive case of meningitis appeared. On November 28 a general quarantine was placed on the camp prohibiting all men from going to the city or assembling in any closed building. This was deemed necessary on account of the great amount of coughing and danger of droplet infection. This quarantine was maintained until December 19 when it was lifted from all organizations, except those in which epidemic meningitis had recently occurred.

---

[1] This statement is in only apparent conflict with Table No. 45, owing to the method of chargin back to the camp of origin incipient cases transferred to another camp.

29. CAMP CODY, N. MEX.

Camp Cody is located 3 miles west of the city of Deming, N. Mex., in the valley of the Mimbres River at an altitude of 4,350 feet. The terrain is high, the drainage good, soil sandy, the water supply exceptionally pure, and the climatic conditions during the greater portion of the year ideal.

The months of November and December were cooler than the average, the lowest temperature being 20° on the 8th of December. There was no rainfall or snowfall.

The soldiers of the camp consisted of National Guard men from the States of Minnesota, Iowa, Nebraska, North Dakota, and South Dakota. These were seasoned soldiers from a territory that contains only a few great cities.

Beginning with the 1st of September the camp grew in strength steadily up to the 1st of November and thereafter remained fairly constant in strength (Chart 38).

Polygon of weekly strength of Camp Cody measured by scale on the left.

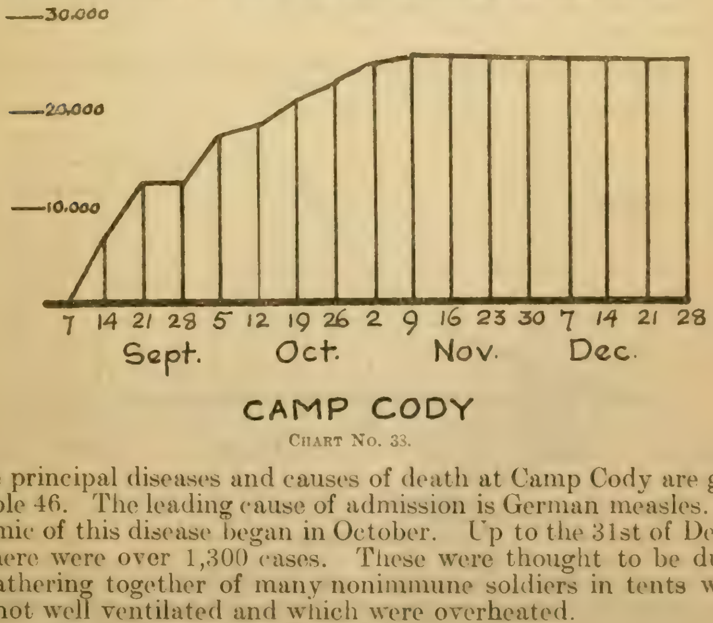

CHART NO. 33.

The principal diseases and causes of death at Camp Cody are given n Table 46. The leading cause of admission is German measles. An pidemic of this disease began in October. Up to the 31st of December there were over 1,300 cases. These were thought to be due to he gathering together of many nonimmune soldiers in tents which vere not well ventilated and which were overheated.

Total	50	414	1,246	890	1	20	25	46

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

There were a good many cases of measles, but no such epidemic as in the camps of the Gulf States. Lobar pneumonia became alarmingly common in December. It was prevailingly a primary disease of which 19 deaths occurred in December and 5 deaths from pneumonia following measles. This minor epidemic lasted through the remainder of the winter.

30. CAMP KEARNEY, CAL.

Camp Kearney is situated on a mesa near San Diego, a city of 50,000 inhabitants, in southern California. The soil is an impervious hardpan which makes poor surface drainage and renders excavation very difficult. The water is supplied from San Diego by a 12-inch main, is filtered and chlorinated by the city, and is safe. The sewerage is disposed of by the standard septic tank and treatment tank for effluent.

Polygon of weekly strength of Camp Kearney measured by scale on the left.

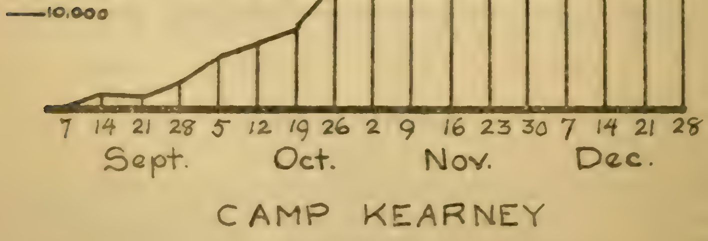

CHART No. 39.

The weather during November and December was mild and ver dry; the lowest temperature recorded was 44° on the 12th of Decem ber. In consequence of the drought the dust was very deep.

Camp Kearney received organizations of the National Guard from Arizona, New Mexico, Colorado, Utah, and California, a region which, except for California, contains few great cities (see Camp Lewis). Few troops came to the camp in September. During October the strength of the camp increased from 4,000 to 18,000 and by the middle of November it had reached 25,000 near which point it remained for the rest of the year (Chart 39).

The leading communicable diseases at Camp Kearney during 1917 are given in Table No. 47.

TABLE No. 47.—*Admissions and deaths, infectious diseases, Camp Kearney, 1917.*

	Admissions.[1]				Deaths.			Total deaths.

Total	26	395	1,494	1,855	4	10	26	40

[1] Figures in parentheses indicate number of colored troops in venereal disease only.

The striking fact in this table is the large number of cases of tuberculosis admitted to sick report—far greater than is shown by any other camp. The only other camps that admitted as many as 100 in any month are Pike (at Little Rock, Ark.) and MacArthur (at Waco, Tex.). Even Camp Lewis, which drew from much the same territory as Camp Kearney, did not have as many as 50 cases in any one month. The large number of cases of tuberculosis at Camp Kearney may be due to a greater laxness on the part of the physicians who examined physically the National Guard, as compared with those who examined the drafted men.[1] Perhaps like many of their forebears who settled this territory, they had a tubercular diathesis.

Measles and German measles both reached high numbers, in November and December, and pneumonia followed in the wake of measles. The frequency of German measles is striking in Camp Lewis also. Again, as in Camp Lewis, venereal diseases ran very high, especially as drafted men came into the camp in November and December. It seems probable that the large incidence of venereal diseases among drafted men from the territory tributary to Kearney may be due to its large mining population. The number of cases that arose *de novo* in command was very small.

Meningitis.—During the last three months of the year, 22 cases were admitted, of which three died. The first cases of this disease appeared in a Colorado regiment a few days after arrival at camp. The entire regiment was quarantined and throat survey made of all the personnel. No secondary cases occurred. About a month later another outbreak occurred, five cases being admitted within 48 hours. They broke out in widely separated parts of the cantonment and in no one of them could infection be traced to previous cases. Mass quarantine of regiment or even companies was concluded to be necessary. Quarantine was made selective and included, first, all tent mates of the sick man: second, his close associates; third, occupants of neighboring tents. These contacts were removed to a quarantine camp, together with their tents and effects. No contacts developed the disease. Later, men in neighboring tents were not quarantined. The outstanding feature of meningitis outbreaks in this camp is that they invariably occurred after dust storms. They have not followed winter rains. All contacts and a great number of other individuals were examined and repeated post nasal smears were made. Even in those found to be carriers of the meningococcus the disease has not manifested itself. The cases were nearly always diagnosed at an early stage. This fact, together with prompt intraspinal treatment at the base hospital is accountable, it is thought, for the comparatively low death rate.

---

[1] However, there were some drafted men at Camp Kearney of whom it is stated that they furnished a large number of noneffectives. It seemed that only a most superficial examination had been made of these men when drafted. It took some time to relieve the command of them.

III. Base Hospitals and Special Services.

At each cantonment an extensive base hospital was built, usually with a capacity for about 1,200 patients. In some camps there was a delay in completing the base hospital until the middle of winter, and this prevented the proper treatment of the sick. In other cases epidemics of unanticipated dimensions showed that the space provided was entirely inadequate. Thus at Camp Pike, with a normal capacity of 1,250, there were on January 14, 1918, 1,785 patients, and there have been as many as 1,850. In this case there was a severe epidemic of measles; and as fast as cases became convalescent they were treated in barracks.

A good picture of the surgical service at a base hospital is afforded by the report from Camp Pike.

From November 1, 1917, to December 1, 1917, operative surgery was carried on in a room of the receiving barracks with but five officers on duty in that service. There were two wards available for surgical patients. Weekly meetings of the surgical staff were held, with a view of putting in force a definite system as soon as the operating pavilion should be opened. This system devised and carried out during the remainder of the year was as follows: The main operating room cared for clean surgery only, and the two operating rooms in this pavilion were labeled "A" and "B." Wards 9, 10, 11, and 12, immediately adjacent, were set aside to take care of the patients on this service. The operating room of the ear, nose, and throat section was denominated "C," with wards 17, 18, and 19 to receive patients on this service. Operating room "D" was to take care of pus cases, with wards 23, 25, and 26; separate operating teams work in each service. The sterilization of dressings required for whole surgical service was finally done in the sterilization room of the operating pavilion. Each ward obtains its own dressings material from the supply officer, cuts and folds them as desired, places them in a clean, labeled pillow slip, and leaves them at the entrance of the operating pavilion at 1 p. m. daily.

The dressings are sterilized and returned to the wards. Each ward then does its own dressings without further assistance from the operating room service. This procedure has greatly simplified and made for efficiency in the dressing of surgical cases. Accident cases were immediately attended to by ward surgeons, and anti-tetanic serum used in all cases. X-ray pictures are made as soon as practicable. Cement floors are in all operating rooms. A satisfactory system for delivery of sterile water was devised by the chief of the surgical service, which meets all requirements. The surgical service has met with the refusal of soldiers with acute appendicitis to submit to operation. Recent orders on the subject of refusal of operation do not meet this condition. Should a patient die without operation his friends can criticize the service for lack of proper treatment. Should operation be performed without the patient's consent and without the proceedings of the board required by recent order, the service would also be open to criticism. It may very well happen that immediate operation is necessary to save life, and there will be no time to convene a board of officers as contemplated. The commanding officer has ordered, in a specific case, that operation should be performed without the patient's consent, it having been decided by consultation that this measure was necessary to preserve the patient's life. Confirmation of this position in similar cases is desired. There were upward of 500 surgical operations of varying nature performed by the surgical service up to January 1, 1918.

BASE HOSPITAL, CAMP PIKE, ARK.—EYE, EAR, NOSE, AND THROAT SERVICE.

The work of this service was at first almost entirely taken up with the examination of malingering. The latter part of October many cases of measles were admitted and ear complications were treated. Up to January 1, 1918, 30 operations for acute mastoiditis were performed, two of these cases being bilateral. The department has treated many cases of tonsilar and paratonsilar abscesses and many cases of laryngitis. It has been realized that probably the most valuable work opened to this department of the surgical service is the seeking out and removing of chronically infected tonsils and the performance of operation for chronic nasal conditions. The limited personnel and the pressure of other work prevented systematic entrance into this field. September 27, 1917, there were two medical officers on duty at this service; October 17, one medical officer; December 5, three medical officers. The equipment was finally all that could be desired, but its arrival was slow.

BASE HOSPITAL, CAMP PIKE, ARK.—MEDICAL SERVICE.

There were many men at work in the hospital when it first opened. Notwithstanding, it was possible to operate all the wards but three. From the opening of the hospital until the end of the year practically all the beds were occupied, and many times it was necessary to place rows of cots in the corridors. There were as many as 1,700 in the hospital at one time. Commissioned personnel in the medical service was insufficient at this time, and sometimes one officer had to see as many as 300 patients. The same was true of the nurses, who worked efficiently and without complaint under adverse conditions. At that time there was no hot water in the wards, and it was a difficult matter to bathe patients.

In the medical service there is a standing order that all serious or doubtful cases must have a consultation with the chief of service, and if he is not available then the next senior officer, and so on down the line, but the consultation must be held, and is an imperative rule in all such cases.

---

[1] Includes broncho-pneumonia, lobar pneumonia, measles (uncomplicated), measles and broncho-pneumonia, measles and lobar pneumonia, measles with complications other than pneumonia, cerebrospinal meningitis (epidemic).

[2] Remaining cases, 1917, not subtracted from admissions.

D. HEALTH OF THE ARMY BY COUNTRIES.

I. Officers.

1. ADMISSIONS.

The admission rate for diseases for officers serving in all countries where American troops were serving in 1917 was 405.64 as compared with 447.40 in 1916.

Table No. 67 shows diseases causing the highest admission rate arranged in the order of their percentage.

2. DEATHS.

The death rate for diseases for officers serving in all countries where American troops were stationed for 1917 was 2.03 per 1,00 as compared with 5.04 in 1916. This great difference was, no doubt due to the fact that a great many officers were commissioned during the year 1917 and the relative age was much lower than the yea 1916.

Table No. 68 shows diseases causing the greatest number of deaths arranged in the order of their percentage. Lobar pneumonia heads the list with a total of 25 per cent.

3. NONEFFECTIVE RATES.

The noneffective rate for diseases for officers in 1917 was 9.76 a compared with 20.31 in 1916.

Table No. 70 shows the diseases causing the loss of the greates amount of time arranged in the order of their percentage.

II. United States Enlisted Men.

1. ADMISSIONS.

The admission rate for diseases for the enlisted men serving i the United States for the year 1917 was 886.81 per 1,000. For 191 the corresponding rate was 608.11. There was consequently a increase of 278.70 for the year 1917 over the year 1916. A considerable amount of this increase was due to the number of infectiou diseases which occurred among the men who had recently bee inducted into the military service.

In the large camps the annual admission rate per one thousan for certain selected infectious diseases, that is broncho-penumonia lobar pneumonia, measles, and cerebrospinal meningitis was 153.38 For the posts other than the camps the corresponding rate was 60.48 Thus is seen at a glance the notable increase in infectious disease which occurred in the camps over the other military posts. Th total rate for these diseases in 1917 was 101.99 as compared wit 23.49 in 1916.

Other infectious diseases have also markedly increased in 191 These diseases were principally mumps and German measles.

CHART No. 40.

In addition to the infectious diseases, as a result of the hasty and many times imperfect physical examinations, a number of men were taken into the service who were within a short time admitted to sick report.

Table No. 71 shows the diseases causing the greatest number of admissions arranged in the order of their prevalence in the United States in 1917.

2. DEATHS.

The death rate for diseases only for enlisted men serving in the United States in 1917 was 5.34 per 1,000. In 1916 the corresponding rate was 2.78. There was thus an increase of 2.56 in 1917 over the year 1916. An examination of the tables shows that for the specia infectious diseases mentioned under admissions, that is—broncho-pneumonia, lobar pneumonia, measles, and cerebrospinal meningitis, the death rate for 1917 was 3.93. The corresponding deatl rate for these diseases in 1916 was .72. The increase for these disease in the year 1917 over the year 1916 was 3.21 per 1,000.

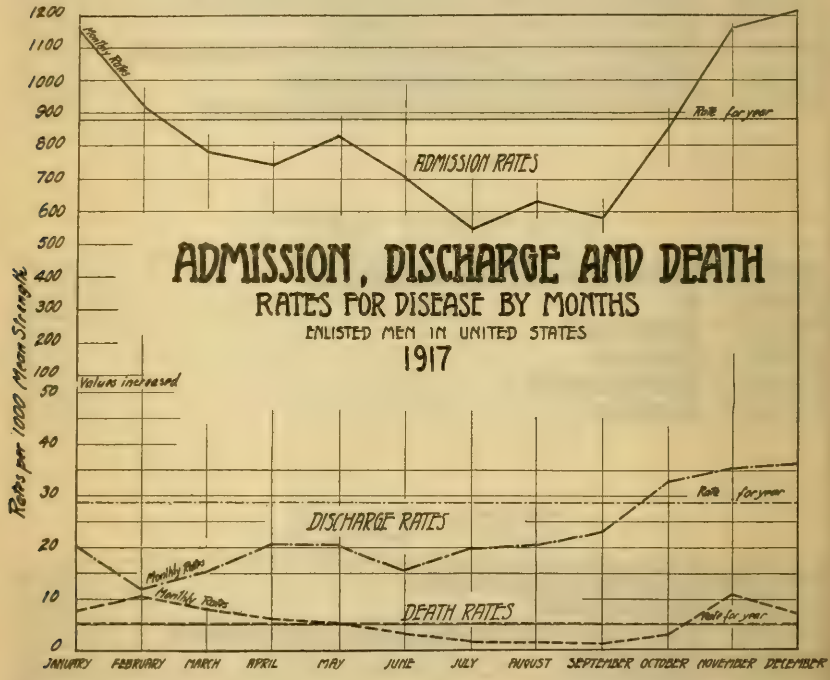

Chart No. 41.

Had it not been for this notable increase in the death rate for thes special infectious diseases in 1917, the death rate for diseases woul have actually been lower in 1917 than in 1916. Excluding thes diseases, the figures would then have been for 1916, 2.08; and for 1917 1.41 per 1,000.

An examination of the figures for the camps and for the militar posts outside of the camps shows that the rate in the large camp was 5.59 per 1,000, while the corresponding rate for posts other tha camps was 2.50. In other words, the death rate in the camps for the special infectious diseases mentioned was more than twice as high as that for the posts outside of the camps. This, no doubt, was due to the fact that as a result of military necessity a large number of men were hastily assembled in these camps under unfavorable circumstances, such as overcrowding in barracks and tents and the inability to secure the proper clothing as early as desirable.

A discussion of the prevalence of these diseases among the troops in the various sections of this country can be found in another place in the report.

Table No. 72 shows the principal causes of deaths arranged in the order of their percentage.

Measles with all complications caused 31.74 per cent of all deaths from diseases. In charging to measles the deaths which occurred as the result of various complications following measles the international rules for the tabulation of causes of death have been followed.

3. DISCHARGES.

The rate for discharges for disability for enlisted men serving in the United States in 1917 was 28.43 per 1,000. The corresponding rate for 1916 was 14.66. There was thus an increase of 13.77 per 1,000.

Table No. 73 shows the principal causes of discharges arranged in the order of their percentage.

It will be noticed that tuberculosis heads the list with 23.15 per cent of the total number discharged for disease.

It will also be noticed that of the total number discharged 15,882 for diseases; in the opinion of medical officers who recommended their discharge, 14,774 were classified as not in line of duty, and 1,108 were classified as having occurred in line of duty. The apparent reason for this large number of discharges was the military necessity of hastily inducting into the service a large number of men often with imperfect examinations.

The work of the physical examinations at camps in the first few months of the year was on the basis of emergency work and was made by a hastily gathered personnel, consisting in part of regimental surgeons and in part of representatives of special boards detailed by the various divisions of the Surgeon General's Office. The examinations were conducted in any sort of a building that could be spared from the pressing need of shelter for troops or anticipated need of medical care. The equipment in many cases consisted of emergency recruiting outfits. The examinations were well organized for the most part by the division surgeons. From Washington assistance and supervision were given by the Sanitary Division, whose inspectors had, however, very many other duties such as the investigation of water, sewage, latrines, control of mosquitoes, flies, extra limital food-booths and epidemiological matters.

As the housing of the physical examinations had been temporary and changeable, so has been the examining personnel. At the beginning the backbone of the examining personnel was a group of special examiners or boards representing divisions of the Surgeon General's Office, such as the Neuro-psychiatric, the Cardio-vascular and the Tuberculosis Boards. For the routine examining the officer in charge had to call upon the regimental surgeons and the base hospital for temporary loans of medical officers. As the physical examinations developed into a continuous function, it became more and more impracticable to borrow medical officers.

The work of making the physical examinations has been faithfully done, but it has failed sufficiently to sort out the fit and the unfit for warfare. This partial failure must be ascribed to the fact that making physical examinations on so great a scale was a new experience for most of the physicians engaged. There were not in this country enough medical men with the proper training to do the work adequately. The cost of the failure must be set down to education. It was impossible for the number of experienced men available to make the examinations properly in the time alloted. Consequently, many men were passed with defects and diseases undetected.

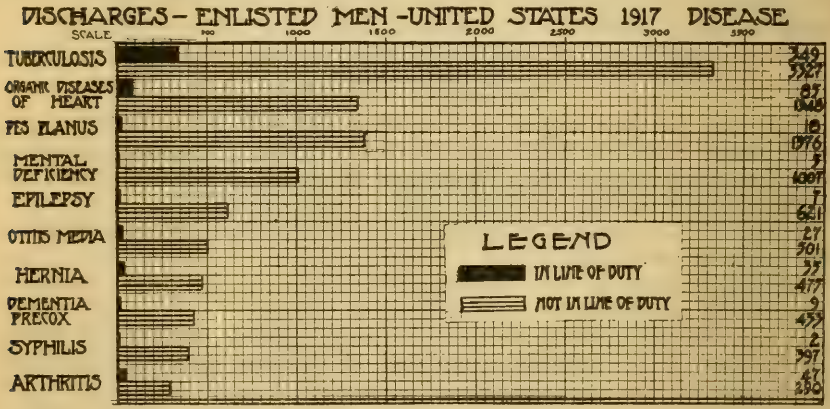

CHART No. 42.

4. NONEFFECTIVE RATES.

The noneffective rates for enlisted men serving in the United States for 1917 was 22.21 per 1,000 as compared with the corresponding rate of 26.30 for 1916. It is interesting to note that in spite of the fact that the admission rate increased and the death rate increased in 1917 the noneffective rate actually decreased.

Table No. 74 shows the diseases causing the loss of the greatest amount of time in 1917, arranged in the order of their percentage.

Measles, which headed the list for deaths, again heads the list for noneffective rates; 11.84 per cent of the total days lost for diseases in the United States in 1917 was caused by measles.

III. AMERICAN EXPEDITIONARY FORCES.

1. ADMISSIONS.

For the troops serving in the American Expeditionary Forces the annual admission rate for diseases per 1,000 in 1917 was 744.17. This rate is to be compared with the corresponding rate of 886.81 in the United States. The rate in the American Expeditionary Forces was consequently lower than that in the United States. This, no doubt, is to be explained by the fact that the troops which were sent to the American Expeditionary Forces were more immune from the diseases on account of the time spent in camps in training and also by the fact that many who had been inducted into the military service with defects or diseases as the result of hasty examinations were eliminated before the troops were transferred to the American Expeditionary Forces.

Table No. 76 shows the principal causes in admission rates arranged in the order of their percentage.

2. DEATHS.

The death rate from diseases for 1917 in the American Expeditionary Forces was 3.00 per 1,000 as compared with the corresponding rate of 5.34 in the United States. Here again, as mentioned under the subject of admissions, the fact that the men while in training in camps in the United States had acquired an immunity to infectious diseases diminished the infectible material before transfer to the American Expeditionary Forces.

Table No. 77 shows the principal causes of deaths, arranged in the order of their percentage. Of the total deaths in Europe lobar pneumonia, broncho-pneumonia, and measles caused 51.83 per cent as compared with 63.54 per cent for the same diseases in the United States. Cerebrospinal meningitis caused 13.87 per cent of the deaths from diseases in Europe as compared with 10.12 per cent in the United States.

3. DISCHARGES.

The rate for discharges for disability of the troops serving in the American Expeditionary Forces for diseases was very low—that is, 1.62 as compared with 28.43 in the United States. All the discharges resulting from diseases which began in Europe were charged back to the American Expeditionary Forces even though the discharge actually occurred in the United States. This very low rate is, no doubt, to be explained by the fact that the troops were very carefully examined before departing for the American Expeditionary Forces and most of the physically unfit were eliminated by being left in this country.

Another factor was that the troops in the American Expeditionary Forces were serving there a comparatively short time during 1917, and consequently the time was too limited for many disabilities to result from diseases occurring there.

Table No. 78 shows the number of discharges in the American Expeditionary Forces, with the diseases arranged in the order of their percentage. Tuberculosis here as in the United States heads the ist, the percentage being 27.03. The number discharged, however, s too small to be accepted as of much value.

4. NONEFFECTIVE RATES.

The noneffective rate for the troops serving in the American Expeditionary Force was 18.13 per 1,000 as compared with 22.21 for he United States.

Table No. 79 shows the diseases causing the loss of the greatest mount of time, arranged in the order of the percentage.

CHART NO. 43.

IV. American Troops Serving in Philippine Islands, Hawaii, Panama, Mexico, China, and on Transports.

1. ADMISSIONS.

Due to the relatively small number of enlisted men of American troops serving in these countries during the year 1917 and the absence of any point of special interest, these countries have been grouped here for the purpose of discussion.

The chief statistics for them, however, are to be found in tables on pages 508–559.

The admission rate for all enlisted men serving in these various countries for the year 1917 was 969.28, as compared with the corresponding rate of 637.87 in 1916 and as compared with the corresponding rate for the United States of 886.81 per 1,000. The admission rate was consequently considerably higher than the corresponding rate for 1916, and higher than the rate for the United States.

Table No. 63 shows a comparison of rates for the principal diseases for these countries as compared with the United States and Europe.

Table No. 80 shows the diseases causing the highest admission rate arranged in the order of their percentage. Gonorrhea here heads the list with 8.78 per cent.

2. DEATHS.

The death rate for American troops serving in these countries was 3.85 for 1917 as compared with 2.30 per 1,000 for 1916.

Table No. 81 shows diseases causing the highest death rates arranged in the order of their percentage. Lobar pneumonia and tuberculosis heads the list with 17.93 and 11.03 per cent, respectively.

Table No. 65 shows a comparison of the principal diseases causing deaths for the troops serving in the United States, Europe, etc.

3. DISCHARGES.

The discharge rate for diseases for American troops serving in these countries in 1917 was 14.78 as compared with 14.02 in 1916 and as compared with 28.43 for 1917 in the United States.

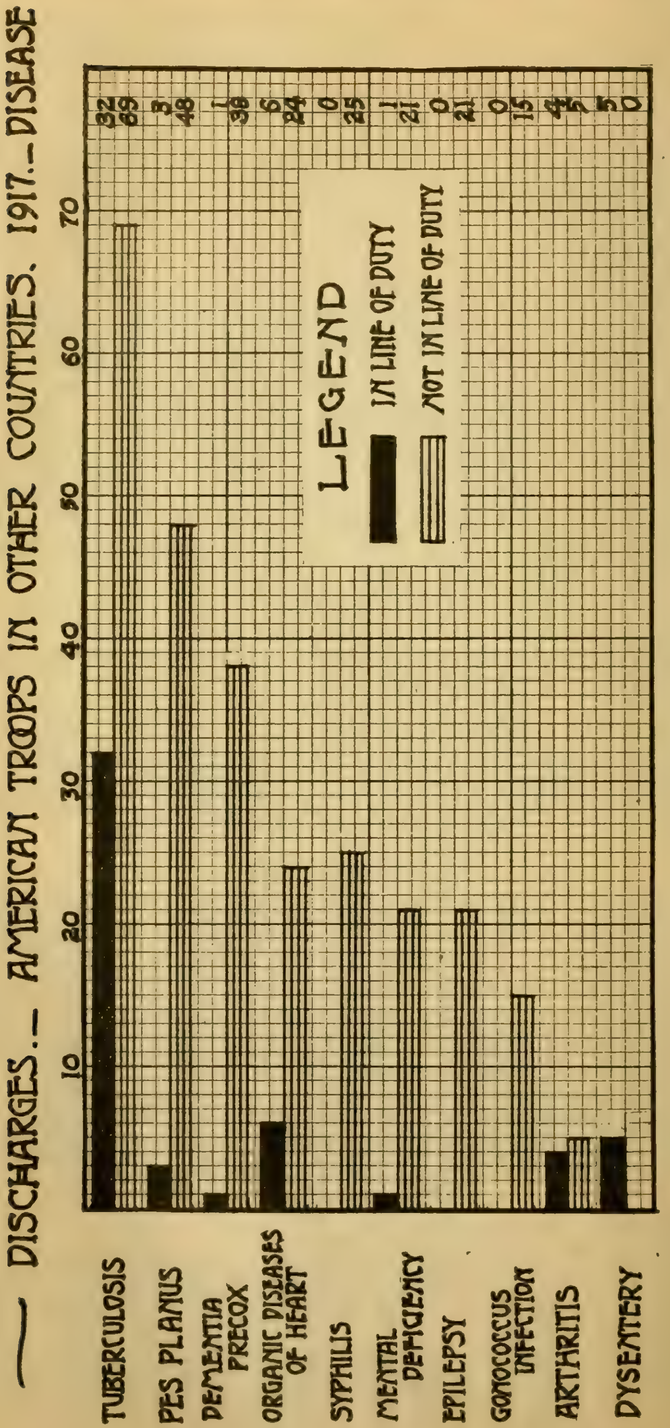
Table No. 64 shows a comparison for the causes of discharge of these countries as compared with the United States, Europe, etc. Here, as elsewhere, tuberculosis caused the greatest number, the ratio per 1,000 being 2.71.

Table No. 82 shows diseases causing the greatest number of discharges arranged in the order of their percentage. Tuberculosis and pes planus head the list with 20.64 and 9.07 per cent, respectively.

4. NONEFFECTIVE RATES.

The noneffective rate for American troops serving in these countries for 1917 was 31.81 per 1,000 as compared with 20.22 in 1916, and with the corresponding rate for troops serving in the United States for 1917 of 22.21.

Table No. 83 shows diseases causing the loss of the greatest amount of time arranged in the order of their percentage. As for admissions, so for time lost, gonorrhea heads the list with 10.33 per cent.



DISCHARGES.— AMERICAN TROOPS IN OTHER COUNTRIES. 1917.—DISEASE

CHART NO. 44.

V. NATIVE TROOPS: PORTO RICANS AND PHILIPPINE SCOUTS.

No detailed discussion of the native troops for the year 1917 is necessary. There was no epidemic or anything of special interest to discuss.

On pages 508–715 can be found the statistics in detail for these troops. The general condition of the health among these troops for the year was satisfactory.

1. PORTO RICANS.

For the Porto Rican troops serving in Porto Rico and Panama the admission rate for diseases in 1917 was 946.18 as compared with 954.97 in 1916. The death rate for diseases for these troops in 1917 was 1.04 as compared with 3.14 in 1916. The discharge rate for diseases was 7.31 in 1917 as compared with 11.52 in 1916. The noneffective rate for diseases was 19.83 in 1917 as compared with 22.88 in 1916. The time lost for each soldier by sickness in 1917 was 7.24 as compared with 9.37 in 1916.

2. PHILIPPINE SCOUTS.

The admission rate for diseases was 481.76 in 1917 as compared with 407.06 in 1916. The death rate for diseases was 1.27 as compared with 2.33 in 1916. The discharge rate for diseases was 4.72 in 1917 as compared with 6.45 in 1916. The noneffective rate for diseases for 1917 was 14.56 as compared with the corresponding rate of 12.43 in 1916. The available time lost for each soldier was 5.32 in 1917 as compared with 4.55 in 1916.

E. SPECIAL DISEASES IN THE ARMY.

I. MEASLES.

1. GENERAL.

Measles is the commonest of the infectious diseases that originate in Army camps. During 1917 there were in the American Army in America and Europe 48,889 admissions to sick report on account of measles. For comparison with the other leading diseases (excepting venereal) it may be noted that there were 44,669 admissions on account of diseases of the tonsils, 47,160 on account of bronchitis, 36,866 on account of influenza, 25,472 on account of mumps, and 28,135 on account of various minor diseases of the intestines. These figures bring out forcibly the fact that to-day the prevalent diseases for recently made and recently mobilized soldiers in the third decade of life are such as involve the respiratory tract.

Map showing the distribution of population of the United States by States. Grades as follows: 1. 0–10 per square mile. 2. 11–45 per square mile. 3. 46–100 per square mile. 4. 101+ per square mile.

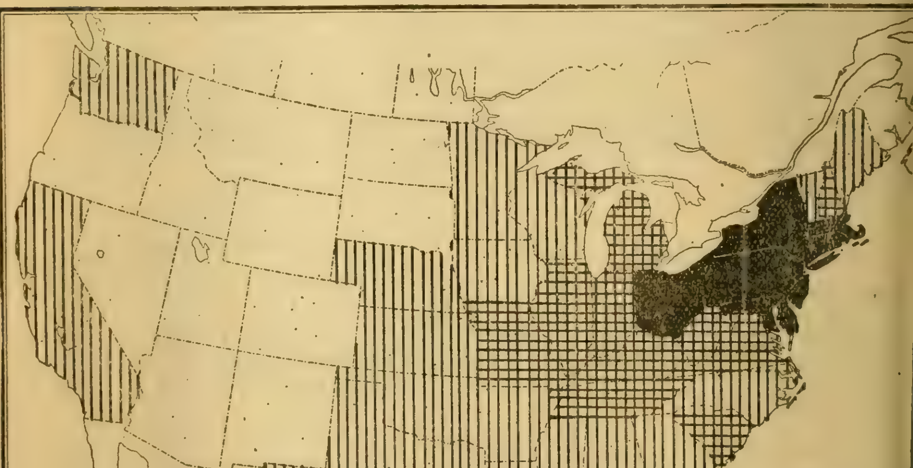

CHART NO. 47.

Measles is doubtless induced by a microorganism, though it has never been isolated. One attack in general gives immunity. With measles is frequently confounded "German measles," but that there is no relation between the two is indicated by the fact that an attack of either disease gives no immunity from the other. In cities measles is so widespread in its distribution that practically every child suffers an attack at or before his early school years. Consequently city children grow up immune to measles. In sparsely settled areas, on the other hand, measles is not universal and many grow to adult life without having become immunized to the disease.

That measles is a disease of childhood is shown by the census returns of mortality.[1] About 88 per cent of deaths from measles occur under 5 years of age and 93 per cent under 10 years. This is not merely because the disease is less fatal in later years, but because immunity has been acquired by the older part of the population through its antecedent infection. Measles ordinarily fails to affect persons much older than 10 years, because such persons have already had measles and so are immune from further attacks. Thus it comes about that in civil life at any year of life, 20 to 30, only about 1 death in 1,000 occurs from measles.

Map showing distribution of admissions to measles, by States of nativity, of enlisted men, charted in four grades. The darker areas indicate greatest resistance to (least incidence of) the disease. The order of States, together with the limits of percentage of incidence of the disease represented by each grade of shading, is as follows: 1. 0–2 per 1,000 male inhabitants, ages 20–29. 2. 2.1–10 per 1,000 male inhabitants, ages 20–29. 3. 10.1–20 per 1,000 male inhabitants, ages 20–29. 4 German measles.

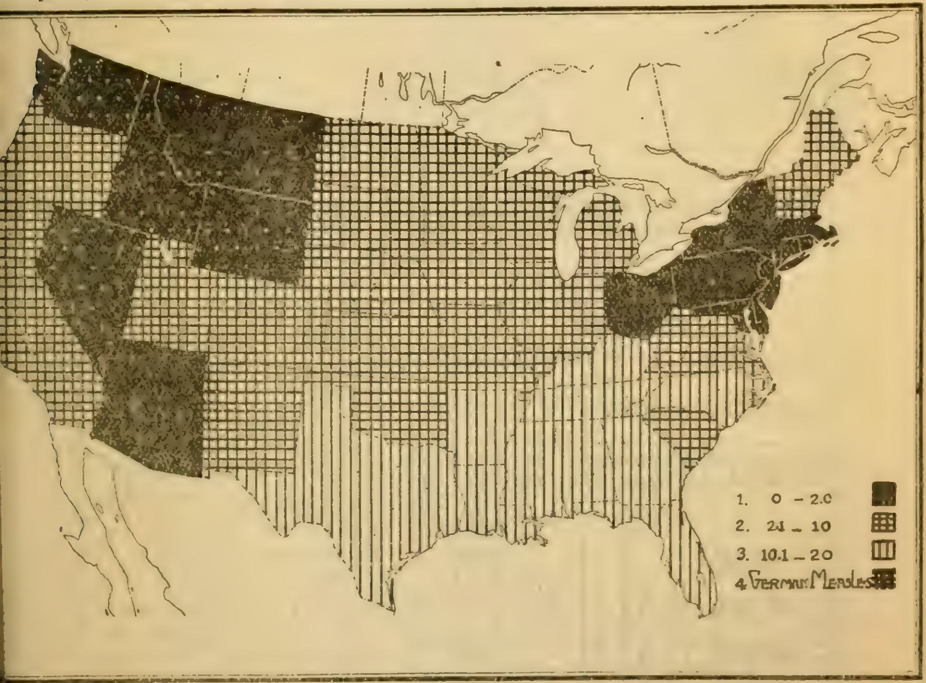

CHART No. 48.

Now the death rate from measles (we have no satisfactory data on morbidity) varies with the density of the population, or with the proportion of the population that lives in cities. This relation is well brought out in Table 84, which gives the distribution of deaths from measles in civil life by age groups of two States (Rhode Island and Connecticut), that are prevailingly urban, and of four States (Kansas, Kentucky, Maine, and Virginia), that are prevailingly rural. It is clear at a glance that in the urban States the deaths occur early, nearly all under 10 years of age, while in Kansas 21 per cent and in Virginia one-third of all deaths from measles are at an age above 10 years.

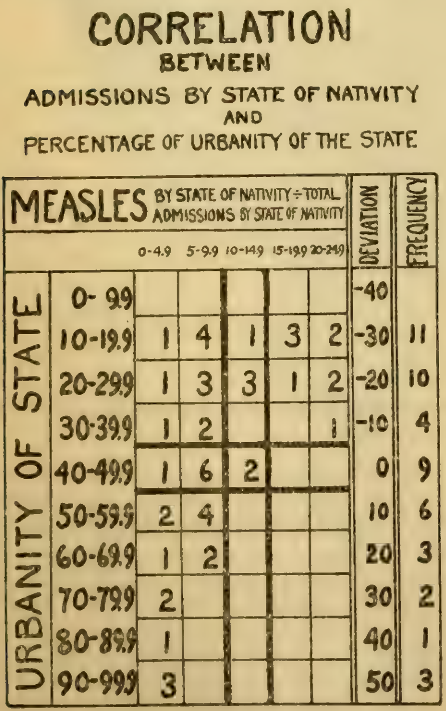
---

[1] U. S. Bureau of the Census: "Mortality statistics," 1915, 16th Ann. Rept., Washington, Government Printing Office.

TABLE NO. 84.—*Comparative distributions of deaths from measles by age groups in urban and rural States, "Mortality statistics," 1915.*

Urban States.	Total deaths, measles.	Under 1 year.	1 year.	2 years.	3 years.	4 years.	5 to 9 years.	10 to 19 years.	20 to 29 years.	30 to 39 years.	40 to 49 years.	50 to 59 years.	60 to 69 years.	70 to 79 years.	Per cent of deaths over 10 years.
Rhode Island	60	19	21	12	3	1	3	....	....	....	....	....	....	....	0.0
Connecticut	61	16	26	7	3	2	3	2	1	1	....	....	....	....	6.7
Kansas	73	17	12	10	5	8	6	4	2	3	2	2	1	1	20.6
Kentucky	85	18	19	11	2	5	5	9	6	2	1	5	2	....	29.4
Maine	18	2	7	2	1	1	3	....	....	....	1	....	....	1	11.1
Virginia	58	10	6	13	2	3	5	11	4	1	....	2	1	....	32 7

The same general result is obtained when we compare the rank of measles as a cause of death in various sections of the country with the density of population in those sections. This is brought out in Table 85 which shows that the death rate for measles, almost exclusively juvenile, is almost twice as high in cities as in the rural part of the registration area of the United States; or, to be exact, as 5.2 is to 2.8 per thousand. For greater New York City the rate is 8.7; for Manhattan Borough, the most densely populated city of the Western Hemisphere, 12.4 per 1,000 of all deaths are deaths from measles. In other boroughs of New York the proportion of deaths from measles varies with the population. This is roughly so with other cities of the country, though there are doubtless other factors at work. The reason for this relation is, the denser the population the more measles and therefore the more deaths from measles. What is true of deaths is probably true of morbidity. Chart 50 shows that the number of cases of measles per 100,000 of the population under 10 years is less in Philadelphia than in New York.



CORRELATION

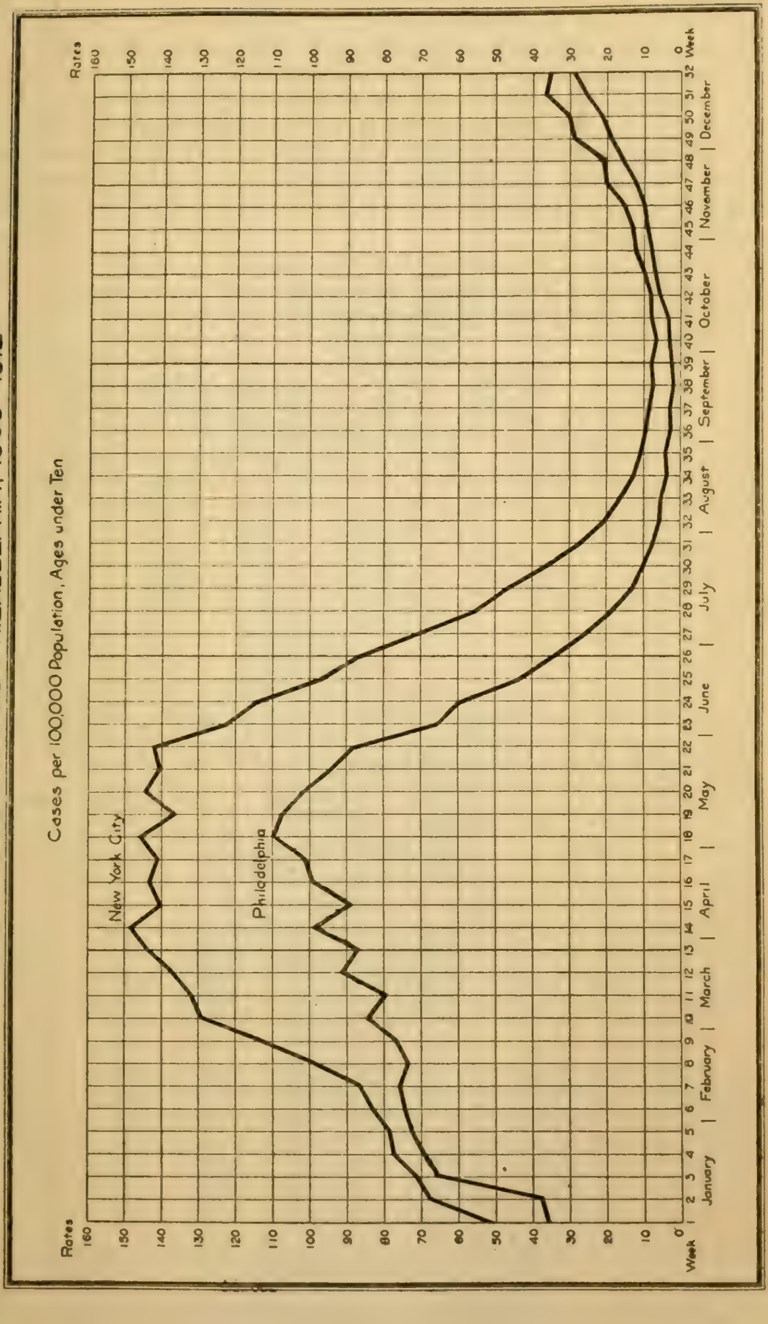
CHART NO. 49.

Again, if the States of the registration area of the United States be arranged in rank in respect to amount of urban population (Table 86)



AVERAGE WEEKLY CASE RATES FROM MEASLES
NEW YORK CITY AND PHILADELPHIA, 1906–1912

CHART NO. 50.

it appears that the proportion of all deaths that are due to measles diminishes, on the whole, with the percentage of urban population; while the average age at death from measles increases, on the whole, with the percentage of rural population. Of course, there are fluctuations in the series, as for example California; but this is a State of great cities and also of great farming areas. So, also, Missouri, while prevailingly rural, is elevated to an unduly high place in the scale of urbanity owing to the two great cities that lie on its borders; consequently it has an unduly high average age of death from measles though a fairly high proportion of the deaths of the State are due to measles.

TABLE NO. 85.—*Comparative frequency of deaths from measles in densely and sparsely populated States and cities, males, United States census, mortality statistics, 1915.*

19	Kentucky	2,365	430	1,935	181	819	.341	11.00

[1] Last 3 figures omitted.

Finally, we may resort to the mathematical theory of chance and plot the "correlation table" showing the relation between the proportion of men in the Army born in any State who were admitted to sick report for measles on the one hand, and the urbanity of their native States on the other. Such a correlation table is shown in Chart 49. Calculating the degree of correlation we find it to be -80 per cent, a high correlation, as correlations go, but inverse (as the minus sign signifies), meaning that the more urban the native State the less susceptible to measles its native born sons in the Army.

All of these tables then point to the same conclusion: in a more densely populated State a larger proportion of the population has had measles and is immune; in a less densely populated State a much smaller proportion has had measles, the rest of the population remains susceptible.

Now, we find that in the Army the natives of different States differed greatly in their susceptibility to measles. If, on one map of the United States the relative density of the population of each State be shown, and on the other the immunity from measles during 1917 by the soldiers in the Army from the different States, then this result appears: The soldiers who were born in the most densely populated States showed the greatest immunity to measles (Charts 47 and 48).

One apparent discrepancy, however, lies prominent on the map. The group of Northwestern States which are States of low urbanity are also States whose soldier sons have low incidence of measles. This matter deserves to be specially considered. The soldiers from these Northwestern States were gathered at Camp Lewis, Wash. The general health of the camp remained good, except for an outbreak of "German measles." By December this disease had reached epidemic proportions, and 1,000 cases were reported sick during that month. Meanwhile there was little plain measles. But the story is not complete without encroaching on the year 1918. As the epidemic of German measles died away, true measles became commoner and rose to about 200 admissions per month. Indeed, for a time in the spring of 1918, Camp Lewis had more true measles than any other camp in the country save one: and that one, Camp Cody, also drew from a rural area. The significance of the apparent substitution for true measles of German measles at Camp Lewis in the early winter of 1917–18 remains a problem for the epidemiologist.

To summarize, the high coefficient of correlation between, and the agreement of maps of distribution of, immunity and density indicate that early acquisition of immunity through crowding is the efficient and the only important factor determining variations in the rate of measles in camps. This factor probably determines 95 per cent of the result.

TABLE No. 87.—*Admissions, measles, by color and complications. United States enlisted men.*

	White.		Colored.		Total.	
	Number.	Ratio.	Number.	Ratio.	Number.	Ratio.
Measles uncomplicated	43,076	78.96	1,082	82.28	44,158	79.04
Measles, lobar pneumonia	680	1.25	23	1.75	703	1.26
Measles, broncho-pneumonia	1,354	2.48	18	1.37	1,372	2.46
Measles, other complications	1,318	2.42	22	1.67	1,340	2.40
Total	46,428	85.11	1,145	87.07	47,573	85.15

2. MEASLES IN RESPECT TO RACE.

It is well known that in certain parts of the globe, like Polynesia, there are races very susceptible to measles and suffering a heavy mortality from it. Is there any difference in this regard between the whites and negroes in the Army? In the Civil War the ratio of total admission during the war on account of measles to mean strength of the Army was, for whites, 145 per 1,000 of strength, and for colored troops, 134 per 1,000. Thus the colored troops appeared to be the less susceptible.

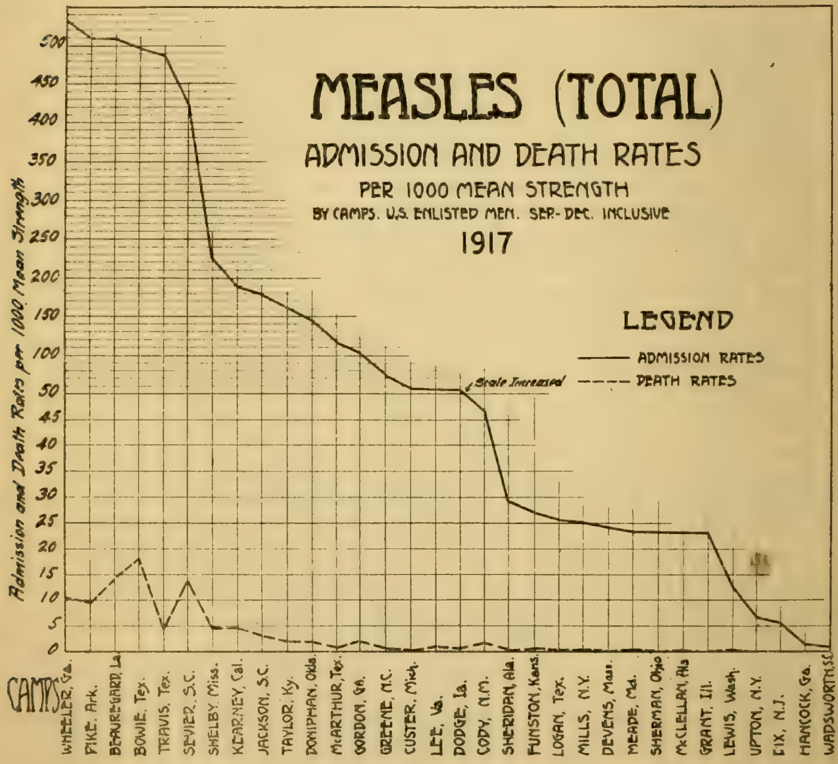

CHART No. 51.

The relations between the races in susceptibility to measles in 1917 is given in Table 87. This table shows that the mean annual rat of admission for measles per 1,000 men is almost the same for white and colored troops, though slightly greater for the latter. Th deaths are too few in either case to make a significant comparison.

3. MEASLES, BY CAMPS.

A brief review of facts given in Chapter C, II, is, on account o the importance of the subject, warranted here.

Of all camps, Wheeler, Ga., had the highest mean annual admis sion rate from measles, namely, 534 per 1,000 men. The epidem iological factors which are responsible for this high rate are plain First, the troops came from Alabama, Florida and Georgia, sparsel settled States. Second, there was a huddling together of men on account of inadequate clothing and heating facilities and on account of cold weather.

The next most affected camp was Pike, Ark., which drew from a southern territory that is only 20 per cent urban. The mean annual rate for measles here was 511 per 1,000 men. There was no crowding here as at Camp Wheeler, but the men lived in barracks and segregation was difficult. The next highest admission rate, 509, is found at Beauregard, La. Here were National Guard troops from nearly the same territory as supplied Camp Pike; the measles was most frequent among the drafted men. Next came Camp Bowie, Tex., with a rate of 499. It is probable that this included some cases of German measles. The soldiers came from Texas and Oklahoma and they were overcrowded in the tents. The soldiers at Camp Travis came also from Oklahoma and Texas; the rate of measles at this camp was 469. Camps Lewis and Cody, both drawing from an extremely rural territory, had each a low morbidity rate (13 and 47, respectively); but this seems to have been compensated for by the highest rates of any camp for German measles (115 and 176, respectively). In Camp Wadsworth, S. C., and other camps occupied by city troops, measles was almost absent.

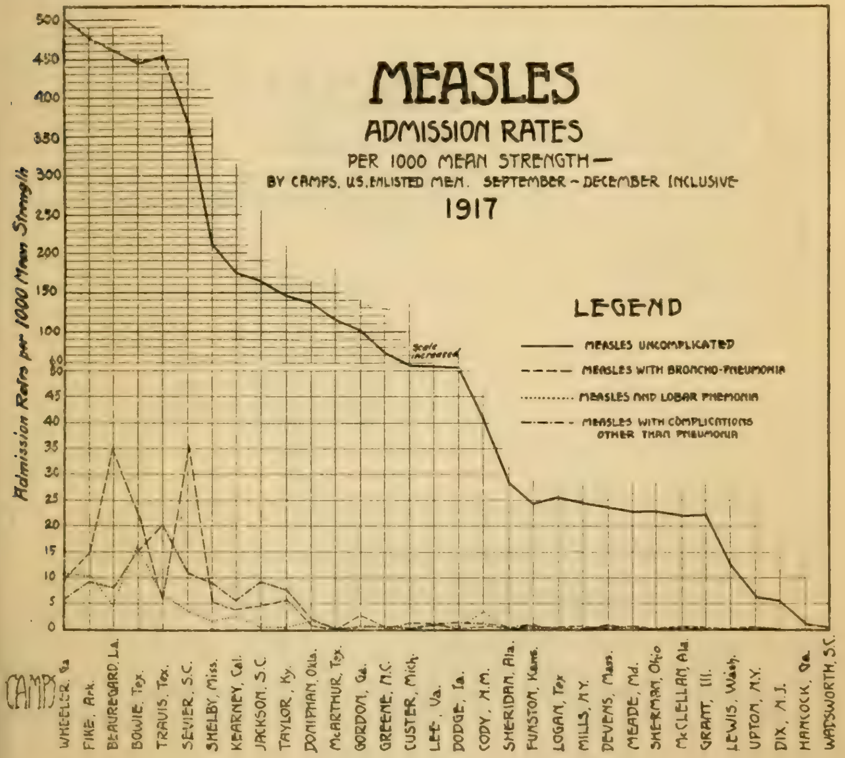

CHART NO. 52.

In the worst afflicted camps, measles paved the way for certain complications that were much more serious than the primary disease.

Thus in Camps Bowie, Beauregard, and Sevier measles was followed in many cases by pneumonia of a very fatal type. On the other hand, at Camp MacArthur, Tex., where the morbidity rate for measles was about 24 per cent that of Camp Bowie, Tex., the morbidity from the complicating pneumonia was only 2.1 per cent that of Bowie. But then the troops at Camp MacArthur were from Michigan and Wisconsin, populous States, and at Custer there was only 1 case of pneumonia following 318 cases of measles; there were, however, a number of cases of streptococcus pleurisy following measles.

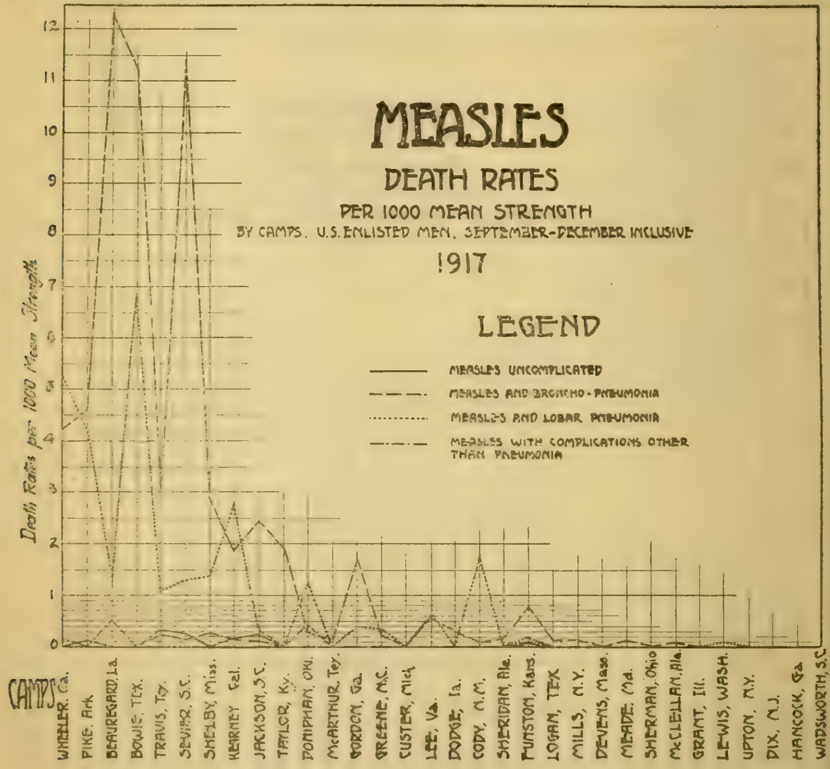

CHART No. 53.

The variations in the frequency with which pneumonia follows measles was partly dependent upon crowding at the hospitals. For where the pressure on hospitals to receive new patients was great, patients convalescing from measles were discharged before fully recovered. Thus a high rate of measles in a camp caused a disproportionally high morbidity rate of pneumonia.

4. COMPLICATIONS OF MEASLES.

Measles proved to be the most important of all diseases in the Army of the United States during 1917 because of the complications that accompanied or followed it. There are on our records 3,421 cases of measles with complications. The most important of these in order of frequency are:

TABLE No. 88.—*Complications of measles.*

	Number of cases.	Recovered.	Died.	Remaining.
Broncho-pneumonia	1,531	627	544	360
Lobar pneumonia	621	233	222	166
Otitis media	557	410	2	145
Broncho-pneumonia, otitis media	76	28	7	41
Broncho-pneumonia-pleurisy suppurative	72	8	45	19
Lobar pneumonia-pleurisy suppurative	52	8	23	21
Lobar pneumonia-otitis media	37	24	6	7
Pleurisy fibrinous	33	29		4
Otitis media-broncho pneumonia	33	19	2	12
Otitis media-mastoiditis	25	13		12
Mastoiditis	25	6		19
Pleurisy suppurative	11	6	2	3

This table gives a sufficiently vivid picture of the grave menace to effectiveness and life that an epidemic of measles brings to the Army and warrants all possible preventive and epidemilogical-prophylactic measures. Measles offers favorable conditions for the development of the pneumococcus and opens the doors, as it were, to the streptococcus. The latter, lodging in inaccessible points, starts centers of proliferation especially in the middle ear and in the communicating mastoid sinus, from which more rarely the meninges become infected. Also the streptococcus may develop in the lungs and pleura, inducing conditions under which a large percentage of the patients die.

5. EPIDEMILOGICAL METHODS.

In some camps a rapid examination of incoming men was made at the railroad station and those with suspicious symptoms of the nasopharynx or with skin erythemas were not permitted to go to the barracks. At the physical examination a more complete investigation was made for acute cases. Quarantine became operative in some camps. Where a command was known to be infected (as at Camp Kearney, Cal.) daily examinations of the entire command were made by medical officers, throats sprayed and precautions taken to provide the best of ventilation and greatest feasible separation of men at night. The cubicle system was installed in some barracks to prevent droplet infection. Special regulations were enforced against emitting discharges of nose and throat upon the ground. Dust aggravated symptoms and dust storms were followed by an increased number of men coming to sick report for pneumonia, so that the practice of spraying roads with oil was introduced in some camps of the Southwest, and with apparently good results.

II. THE PNEUMONIAS.

It has been well said that, as typhoid fever was the preeminent medical problem of the Spanish-American War, so pneumonia was of the present war in the winter of 1917–18. Pneumonia has, indeed, always played an important part in war. In our Civil War, there were 61,202 cases of "inflammation of the lungs" out of 5,417,360 admissions of white soldiers for disease, or 1.13 per cent of admissions. The 61,202 cases occurred during four years when the mean strength of the white troops of the Army was 468,275, giving a mean annual rate of 32.7 per 1,000 men. Moreover, there were 14,738 deaths from pneumonia among a total of 128,930 deaths from disease, or 11.42 per cent of deaths.

Our advances in the knowledge of the pneumonias have been so great that it will not be easy to compare the data of 1917 with those of 1861–1865. Nevertheless the attempt will not be without interest.

As is well known, the pneumonias may be classified in various ways. By the microorganisms involved they may be classified as pneumococcic and streptococcic pneumonias. Of the former, four different types have been isolated. Again, pneumonias may be classified anatomically into the lobar and broncho-pneumonias. Since in 1917 it was not practicable in camps to differentiate the types of pneumococcic pneumonia to study the other microorganisms involved, cases were reported as of the two anatomical types, lobar and broncho-pneumonia.

The mass statistics of the pneumonias in the total Army in the United States, 1917, are as follows:

TABLE NO. 91.—*Pneumonia, primary and secondary.*

	White (mean strength 545,518).			Colored (mean strength 13,150).			Total (558,668).		
	Admissions.	Deaths.	Case mortality.	Admissions.	Deaths.	Case mortality.	Admissions.	Deaths.	Case mortality.
Broncho-pneumonia	1,372	193	14.07	96	9	9.38	1,468	202	13.76
Lobar pneumonia	6,258	663	10.59	706	84	11.90	6,964	747	10.73
Pneumonia, unclassified	44	3	6.82	3	..	....	47	3	6.38
Measles and broncho-pneumonia	1,354	618	45.64	18	4	22.22	1,372	622	45.33
Measles and lobar pneumonia	680	263	38.68	23	3	13.04	703	266	37.84
Total primary pneumonia and pneumonia complicating measles	9,708	1,740	17.92	846	100	11.82	10,554	1,840	17.43
Total for all diseases for United States Army, 1917	481,434	2,822	.59	13,997	162	1.16	495,431	2,984	.60

From this table it appears that the total of all the various classes of pneumonia together were responsible for 2.02 per cent of total admissions for all diseases of white troops (or nearly double the proportion reported in the Civil War), 6.04 per cent were of admissions of colored troops, or, combined 2.13 per cent for all troops. Also, the pneumonias were responsible for 61.7 per cent of the deaths among all troops, the rate for white and colored being the same. The case mortality is 17.9 per 100 for white troops, or about three-quarters that of the Civil War. The case mortality for colored troops is 11.8 per 100 and for white and colored troops together 17.4 per 100.

It appears, then, that while pneumonia is relatively more important in 1917 as a cause of death than it was in 1861–1865 (becaus other diseases are less important), the case mortality for pneumoni is greatly diminished. This comparison must, however, be accepte with caution. The rates for 1917 cover only the autumn and earl winter, when pneumonia is at its height. The Civil War record covers a number of summer periods, when there is little pneumonia The two types of pneumonia that have to be considered are, as stated lobar pneumonia and broncho-pneumonia, and these may occur eithe as primary or as secondary to measles.

1. PRIMARY LOBAR PNEUMONIA.

A. GENERAL.

This was the most fatal single disease that affected our Army durin 1917, excepting only measles and its complications grouped as single cause of death. Lobar pneumonia is charged with 6,96 admissions and 747 deaths in the total Army in the United States

The course of the disease in the whole Army, United States, b months, is shown in Table 92.

TABLE No. 92. *Lobar pneumonia, by months.*

Months.	Admissions.		Deaths.	
	Cases.	Mean annual rate.	Cases.	Mean annual rate.
1917.				
September	79	1.89	5	0.12
October	626	9.63	46	.71
November	1,644	23.09	217	3.05
December	1,823	25.51	175	2.45
Total	4,172	16.72	443	1.77

As was to have been expected with a rapidly growing Army, the number of admissions and deaths from the pneumonias increased from September to December, but the increase of admissions was proportionately much faster than the increase of the Army, as is shown by the steady rise of the mean annual rate per 1,000 men. The census returns of morbidity in civil life show that December to March are the months of greatest fatality for pneumonia and bronchopneumonia. In the Army, however, the number of deaths does not increase in the last month of the year, as it did in the preceding months, due to incompleted cases.

Considering the distribution of lobar pneumonia by countries, it appears that there were 6,964 admissions in the United States, giving a mean annual rate of 12.47; and 335 in Europe, giving a rate of 7.34. The smaller rate in Europe is undoubtedly to be explained by the fact that the European troops were seasoned men, while those of the United States were mostly fresh from civil life, of all degrees of susceptibility, and placed under conditions of crowding that favored the spread of communicable diseases.

The influence of "seasoning" of the troops and of smaller posts is indicated by the fact that the 1,700 cases that occurred among troops of the Regular Army constituted a rate of 8.76, while the 1,462 cases in the National Army gave a rate of 9.17. The rate in the National Guard camps was still higher, namely, 16.12, largely due to the worse living conditions to which they were subjected. The death rate of Regulars and National Army was exactly the same, namely, 0.93, while that of the National Guard was 1.73. It is to be noted that not all of the National Guard camps contained seasoned troops, despite the experience of many of them on the Mexican border in 1916. This is partly because the National Guards received considerable fresh ncrements in the spring of 1917 and because many drafted men were ntroduced into the National Guard camps. These introduced raw recruits proved a great danger to the better seasoned troops in the camps where they were placed.

Is there any racial difference in susceptibility to lobar pneumonia, primary? In the United States the morbidity rate (admission ÷ strength) for whites was 11.47, for colored 53.69 (Table 91); and this excess of susceptibility of the colored troops held in all three armies. But whereas the colored troops of the Regulars were only three times as susceptible as the white troops of that Army, the colored troops of he National Army were eight and one-half times as susceptible as white troops. This is evidence that the members of this highly susceptible race had in the Regular Army gained relative immunity either through the elimination of the more susceptible or otherwise. As for deaths, the colored Regulars showed a death rate (3.60) that was four times that of whiteRe gulars (0.93); while of the colored command of the National Army the death rate was 9.48, or ten times that of the white command (0.93). These figures show not only that raw colored troops are less immune, but also that they are less resistant than raw white troops, and their lack of resistance to death is more pronounced than their lack of immunity. That is, they are about eight and one-half times as apt to fall sick with lobar pneumonia and the sick are about one-third more apt to die.

Map showing distribution of admissions for lobar pneumonia, by State of nativity of enlisted men. Charted in four grades. The darker areas indicate greatest resistance to (least incidence of) the disease. The order of States, together with the limits of percentage of incidence of the disease represented by each grade of shading, is as follows: 1. Below 0.34: Rhode Island, Delaware, Wyoming, New Jersey, New York, Pennsylvania, Massachusetts, Connecticut, Washington, West Virginia, Utah, North Dakota, Maine. 2. 0.39–0.34: District of Columbia, Oregon, Nevada, Idaho, Arizona, California, Michigan, Maryland, New Hampshire. 3. 1.3–0.4: Colorado, Minnesota, Ohio, South Dakota, New Mexico, Illinois, Wisconsin, Montana, Oklahoma, Utah, Indiana, North Carolina, Virginia, South Carolina, Iowa, Kansas, Missouri, Tennessee, Nebraska, Kentucky. 4. 1.4 and above: Louisiana, Arkansas, Mississippi, Texas, Alabama, Georgia, Florida.

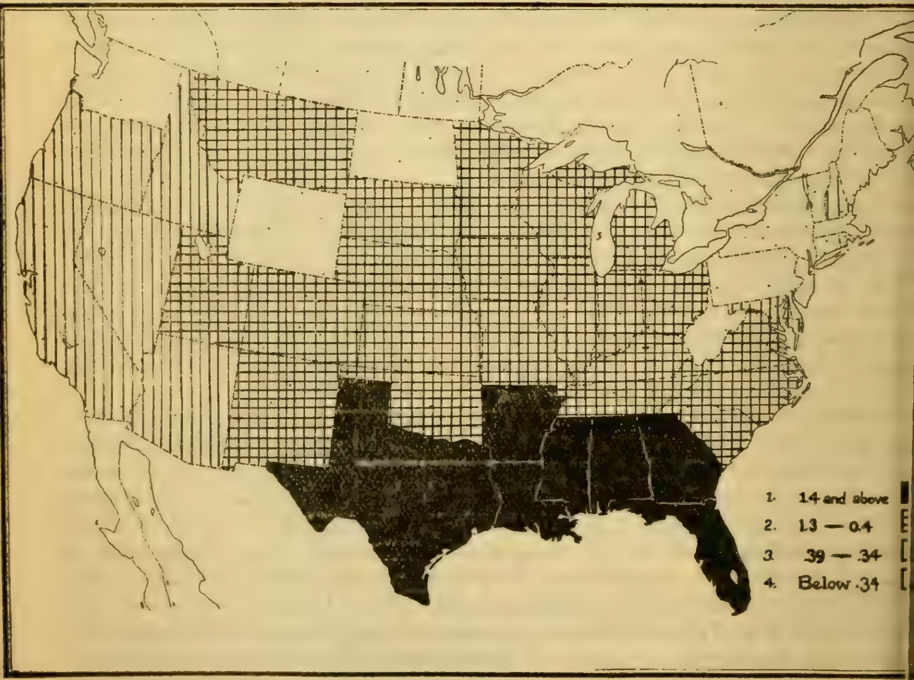

CHART No. 54.

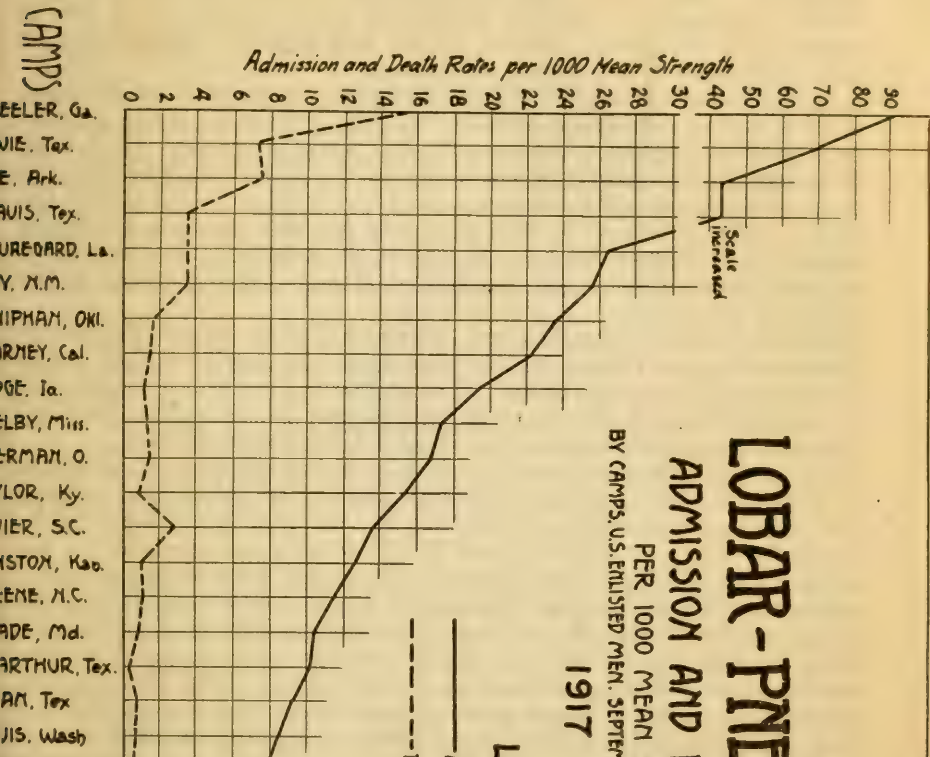
B. LOBAR PNEUMONIA, BY STATE OF NATIVITY.

Next we have to consider the distribution of lobar pneumonia by State of nativity of the troops. As Table 60 shows, the heaviest incidence of pneumonia is found in the Gulf States and Arkansas. The next highest incidence is the middle zone of States from souther

Tennessee and Oklahoma north to Pennsylvania (and western Virginia) and the Canadian border west of the Great Lakes. But in the Pacific and Great Basin States the rate was low and still lower in the



New England and Middle States. Why this difference in amount of lobar pneumonia in enlisted men from the different States? There are various possible explanations.

1. The variation may be coincident with the density of the population of the native State or with the number of large cities that it contains. This factor undoubtedly plays a part, yet it is not the whole explanation. For the amount of lobar pneumonia is low in troops from Wyoming, Nevada, Idaho, and Arizona—States without large cities and with a sparse population.

2. The variation may be influenced by the temperature of the place of encampment during the winter months. But this is not a determining factor, for Camp Wadsworth, S. C., and Camp Sevier, S. C., both National Guard camps, had practically the same temperature; yet the morbidity rate for pneumonia of the former was 4.25; of the latter, 13.84. Also, it is clear that cold weather was not a primary cause, for at Camp Custer in the North the admission rate was 5.38; while at Camp Pike, which also housed National Army troops in the South, it was 43.77.

3. The variation may depend on conditions in camp. There was overcrowding at Travis, which drew from the territory that shows so very black upon the chart. Yet at Camp Pike, there was no important crowding in the barracks, which were also those of a National Army cantonment, and yet there was much pneumonia here.

To get the broadest possible view of the conditions of incidence of lobar pneumonia in the different sections of the Army, a chart (No. 56) has been drawn up showing the distribution of lobar pneumonia by State of nativity and State of occurrence combined, for white troops in the United States. There are 5,929 cases in troops whose nativity is known. When the States are arranged by mean January temperature of both State of nativity and State of occurrence, then we find that there were 3,344 soldiers born in warm States, who acquired lobar pneumonia in warm States; 1,315 born in cold States, who acquired lobar pneumonia in warm States; 492 soldiers born in warm States who acquired lobar pneumonia in cold States; and 750 soldiers born in cold States who acquired lobar pneumonia in cold States.

Assuming the total strength of the Army (that is, the number of men who were liable to an attack of pneumonia) at 1,325,000 men and assuming the values 1,025,000 and 300,000 as a fair approximation to a number of troops in the warmer States, and in the colder States, respectively, and having found by calculation that the number of troops born in the warmer States and the colder States are as 500,000 to 525,000, then we may calulate the ratio of the incidence of lobar pneumonia, in each of the quadrants of Chart No. 56. The results of such calculation are given in the following table:

	Number.	Cases.	Ratio.
Born in warm States and encamped in warm States	500,000	3,344	6.67
Born in cold States and encamped in warm States	525,000	1,315	2.50
Born in warm States and encamped in cold States	121,700	492	4.04
Born in cold States and encamped in cold States	178,300	750	4.21

If all these approximations are warranted then the following calculations appear to be justified. Lobar pneumonia affected troops in the following order of susceptibility:

1. Born in warm States and encamped in warm States.
2. Born in cold States and encamped in cold States.
3. Born in warm States and encamped in cold States.
4. Born in cold States and encamped in warm States.

Thus we may say, that as with broncho-pneumonia, so with lobar pneumonia, the soldiers who were born in the warmer States and encamped therein, proved far more susceptible than those born in the colder States and encamped in the warmer States. Furthermore the following difference appears: The troops born in coastal States and those held in the canps bordering on the Atlantic and Pacific Oceans, suffer less from lobar pneumonia than do those in the interior of the country. This is not due merely to the fact that the Coastal States have a denser population. West Virginia, which has a small population, nevertheless produced troops relatively immune to pneumonia. Charts and table agree in showing the heavy incidence of lobar pneumonia in troops of the Gulf States.

In general, the rate of admission on account of lobar pneumonia for all troops born in the warmer States is about 0.62 per cent, while of those born in the colder States is 0.30 per cent.

C. LOBAR PNEUMONIA, BY CAMPS.

Turning now to the camps, we find the admission and death rates to vary greatly. The highest admission rates are at Wheeler, Ga., 106.15; Bowie, Tex., 70.33; Pike, Ark., 43.77; Travis, Tex., 43.76 and Beauregard, La., 26.55. These are all camps where great epidemics, both of measles and pneumonia occurred as is discussed in the chapter on measles. On the other hand, the lowest admission rates are found at Hancock, Ga., 1.47; Devens, Mass., 2.86; Dix, N. J., 4.25; Wadsworth, S. C., 4.25; and McClellan, Ala., 4.65. Three of these are southern camps but they sheltered northern troops—Hancock, troops from Pennsylvania; Wadsworth, troops from New York; and McClelland, troops from New Jersey, Delaware, Maryland and District of Columbia. Thus it appears that, as in the case of measles, so in the case of pneumonia, troops fron the sparsely settled States, especially the southern States, were liable to lobar pneumonia while troops from the densely settled northern States were relatively immune from pneumonia.

2. PRIMARY BRONCHO-PNEUMONIA.

Next to measles and its complications, primary lobar pneumonia and cerebrospinal meningitis, primary broncho-pneumonia caused more deaths than any other camp disease. There were in the United States 1,468 admissions of enlisted men for this disease and 202 deaths. Thus the case mortality 137 per 1,000 is contrasted with the case mortality of primary lobar pneumonia, of 107 per 1,000. Similarly, broncho-pneumonia complicating measles had a case mortality of 453 per 1,000 as contrasted with the case mortality of measles complicated with lobar pneumonia of 378. Broncho-pneumonia is thus a more fatal disease than lobar pneumonia, due proba-ly to the fact that the virulent infection with streptococcus haemo-yticus tends to take the bronchial form. Measles followed by

broncho-pneumonia is, indeed, the most fatal combination of diseases known in camps.

Map showing distribution of broncho-pneumonia (primary), by State of nativity, United States enlisted men. Rate per 1,000 of the adult male civil population of each State (age 20 to 29 years), in five grades, the darkest representing heaviest incidence of broncho-pneumonia. Grades as follows: 1. 0.40: Arkansas, Louisiana, Georgia, Texas, Mississippi, Florida. 2. 0.15–0.40: Alabama, Tennessee, South Carolina, Vermont, Indiana, New Mexico, Kentucky, North Carolina, Delaware, Missouri. 3. 0.09–0.15: Colorado, Kansas, New Hampshire, Virginia, Oklahoma, California, Nebraska, Iowa, Maine, Maryland, Ohio, West Virginia, Wisconsin. 4. Below 0.09: Illinois, Michigan, New Jersey, Oregon, Rhode Island, Connecticut, Minnesota, New York, Pennsylvania, Utah, Massachusetts, Montana, Washington, South Dakota, District of Columbia. 5. Arizona, Idaho, Nevada, North Dakota, Wyoming.

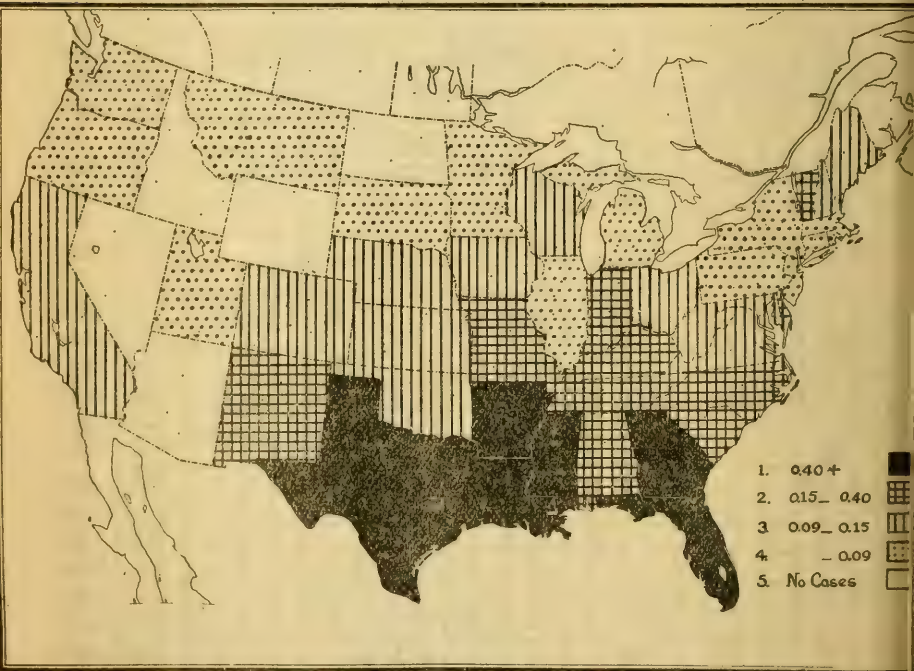

Chart No. 57.

The difference in racial resistance to broncho-pneumonia is shown in the following table:

Admission rates for broncho-pneumonia.

	White.	Colored.	Total.
United States	2.51	7.30	2.63
Europe	4.05	20.75	4.32

According to this table there are relatively about three times as many colored as whites who show the symptoms of broncho-pneumonia (primary), but the case mortality of primary broncho-pneumonia is less among colored than white troops. Thus the colored troops proved to be more resistant to broncho-pneumonia than white troops are, while they are less resistant to lobar pneumonia than white troops.

The distribution of broncho-pneumonia by nativity and by State of occurrence in white troops is shown in Chart 59. There are 888 cases

of broncho-pneumonia from troops who were natives of warm States and were located in warm States. There were 252 cases from troops born in cold States and located in warm States. There were 54 cases among troops that were born in warm States and were located in cold States and 105 cases among troops born in cold States and located in cold States. Putting the total strength at 1,325,000 and making assumptions as in the case of broncho-pneumonia and by means of similar calculations, we reach the following rates of incidence per 100 men of admissions for broncho-pneumonia.

	Number.	Cases.	Ratio.
Born in warm States and encamped in warm States	500,000	888	1.78
Born in cold States and encamped in warm States	525,000	252	.48
Born in warm States and encamped in cold States	121,700	54	.44
Born in cold States and encamped in cold States	178,300	105	.59

If all these approximations are warranted, the following conclusions seem to be justified:

Broncho-pneumonia affected troops in the following order of susceptibility:
1. Born in warm States and encamped in warm States.
2. Born in cold States and encamped in cold States.
3. Born in cold States and encamped in warm States.
4. Born in warm States and encamped in cold States.

Comparing the distribution of lobar and broncho-pneumonia by States of occurrence, it appears that lobar pneumonia was relatively the commonest in the Gulf States and Arkansas and least common in the New England and Middle States and West Virginia. It is also low in Wyoming and Washington. The incidence of broncho-pneumonia (which is less common and more fatal) is somewhat different. Alabama no longer falls in the class of heaviest incidence of this disease. New England falls into three grades. Still the warmer States are clearly those of greatest incidence of the disease.

In respect to the territory from which camps draw there is a smaller difference between lobar and broncho pneumonia. Whereas the natives of Coastal States are little affected by lobar pneumonia, this is not true of broncho-pneumonia. In general, the occurrence of lobar pneumonia seems to be more dependent upon meterological conditions than is that of broncho-pneumonia.

3. MEASLES AS PRIMARY TO PNEUMONIA.

Pneumonia, primary, either lobar or bronchial, is a dangerous disease, both because of absolute number of admissions to sick report and because of its absolute mortality; but these diseases become much more dangerous when they occur as complications to measles. Thus, of 1,354 admissions on account of broncho-pneumonia complicating measles in white troops 45.6 per cent died, and of 680 admissions on account of lobar pneumonia complicating measles, 38.7 per cent died. The colored troops did not suffer relatively as much as white troops from these complications; though primary lobar pneumonia was relatively more numerous and relatively more fatal with the colored troops than with white troops.

The relation of measles to the pneumonias is not so much that pneumonia depends on measles for admission to the body, since there are nearly four times as many cases of primary pneumonia as of pneumonia following measles. Also, only a small proportion of cases of measles are followed by pneumonia; out of 47,573 cases of measles in the United States only 2,075 were followed by pneumonia. The striking fact is that when pneumonia does follow measles it is so often fatal. Measles diminishes resistance. It is to be noted, moreover, that when pneumonia follows measles, pneumonia is thrice as frequently of the bronchial as of the lobar type, though in primary pneumonia the lobar type is five times as common as the bronchial; and when broncho-pneumonia does complicate measles, it is fatal in 45 per cent of the cases, though when primary it is fatal in only 14 per cent of the cases. This is probably because the antecedent measles has diminished resistance or else has permitted a more virulent organism to enter into the tissues, namely streptococcus haemolyticus, which produces the so-called interstitial broncho-pneumonia. In negroes this especial morbidity of broncho-pneumonia complicating measles is striking. Thus, primary broncho-pneumonia is less fatal in that race than primary lobar pneumonia, but, as a complication of measles, broncho-pneumonia is nearly one and three-quarters more apt to end fatally in that race than lobar pneumonia. The colored race resists obar pneumonia following measles, but it is relatively unresistant to broncho-pneumonia complicating measles. Also, this relative predominance in the mortality of broncho-pneumonia over lobar pneumonia complicating measles is greater in the colored than in the white troops.

III. VENEREAL DISEASES.

The venereal diseases constitute a group of great social as well as medical interest. Communicated, for the most part, by illicit sexual intercourse and chiefly by prostitution, their prevalence constitutes a rough measure of the failure of education and other social influences to secure control of the sex impulse on the part of the male population. Since instruction as to the importance of such control is generally diffused, the prevalence of venereal disease is a partial measure of the inability of a part of the population to inhibit its sex impulse. Moreover, since the amount of prostitution can be diminished by repressive measures, the frequency of the venereal diseases in any region is partially influenced by the completeness of such repressive measures.

1. CLASSIFICATION.

The venereal diseases are grouped in our statistics into three classes, syphilis, chancroid, and gonococcus infection.

2. SUMMARY OF STATISTICS.

The total number of cases of admission to sick report for venereal diseases for the total enlisted men, American troops, for the year 1917 was 71,955. The total number of days lost in hospitals or at quarters on account of these diseases was 875,553, or 2,399 years. Of these, 1,415 years were lost from gonorrhea, 584 years from syphilis, and 400 years from chancroid. The importance of these diseases in producing ineffectives in the Army is thus obvious.

Considering now, for a moment, only the admissions to sick report of enlisted [1] men in the United States, we find there are 63,586 of them. Of these 59,503 are for white troops, 4,083 for colored troops. This gives a ratio per 1,000 mean strength of 109.1 for the white troops and 310.5 for the colored, the colored being 2.8 times the more numerous relatively.

---

[1] The term enlisted men includes privates and noncommissioned officers of all grades, whether they have enlisted in the Army by voluntary enlistment or by draft.

Distributed by the three principal diseases we have the following rates and the multiple that the colored rate is of the white rate:

Disease.	Rate per 1,000 mean strength.		
	White.	Colored.	Multiple.
Syphilis	14.22	54.68	3.85
Chancroid	12.38	52.78	4.25
Gonorrhea	82.48	203.04	2.46

From these figures we may conclude that, not only is venereal disease commoner among colored than white troops in the United States, but that the separate diseases are commoner in the order, chancroid, syphilis, gonorrhea.

Map showing distribution of ratio of total admissions for venereal diseases per 1,000 mean strength in National Army camps. 1. 230–210. Travis, 229.39; Lewis, 211.15. 2. 180–140. Sherman, 178.29; Dix, 164.17; Gordon, 163.41; Meade, 156.23; Taylor, 142.25. 3. 130–55. Custer, 129.26; Dodge, 127.60; Pike, 113.00; Funston, 86.36; Lee, 77.92; Grant, 55.80. 4. 50–40. Upton, 47.44; Jackson, 46.74; Devens, 43.55. The States that contributed recruits to a given camp are marked with the symbol that indicates the ratios of admissions at that camp.

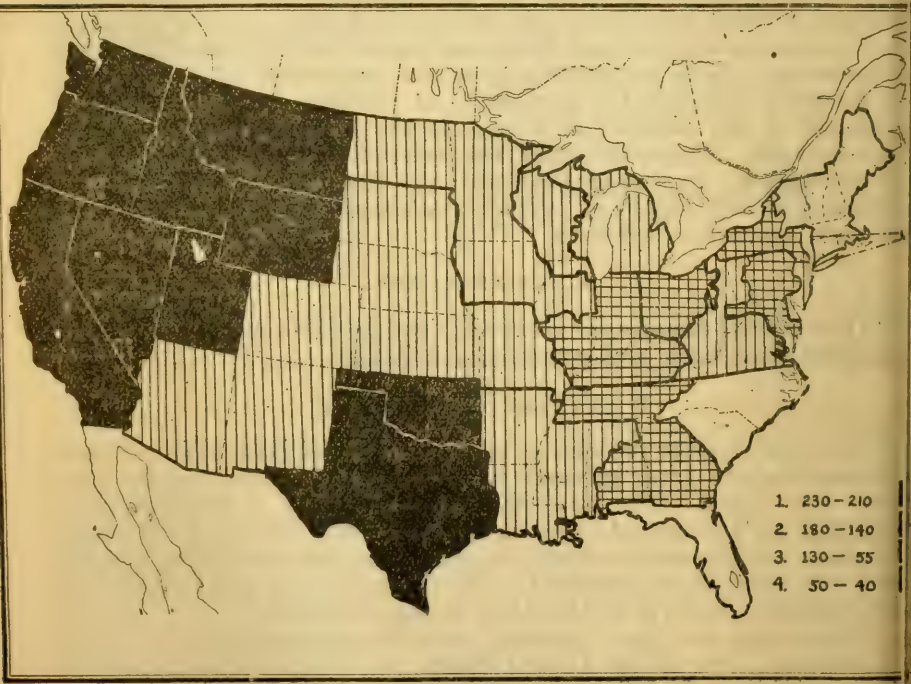

CHART NO. 60.

Considering the case morbidity, it appears that in syphilis the ,7557 whites admitted were 161,788 days on sick report, an average of 20.8 days; in chancroid the 6,758 whites admitted were sick on an average of 15.4 days; in gonorrhea the 44,990 white admissions were sick on an average of 9.7 days. Among the colored enlisted men, on the other hand, the average case morbidity was for syphilis 19.5 days;

for chancroid, 13.8 days; for gonorrhea, 6.3 days. A comparison of the last two paragraphs leads to the conclusion that (provided white and colored venereal cases receive similar treatment) a case of gonorrhea runs a much less serious course among colored than white troops.

3. CRITIQUE OF STATISTICS.

We now come to a group of inquiries, such as relative frequency of venereal disease in the Army and in civil life, in various branches of the Army, etc., for which significant answers can only be obtained after the nature of the Army statistics has been more fully considered. To such a consideration, therefore, we now turn.

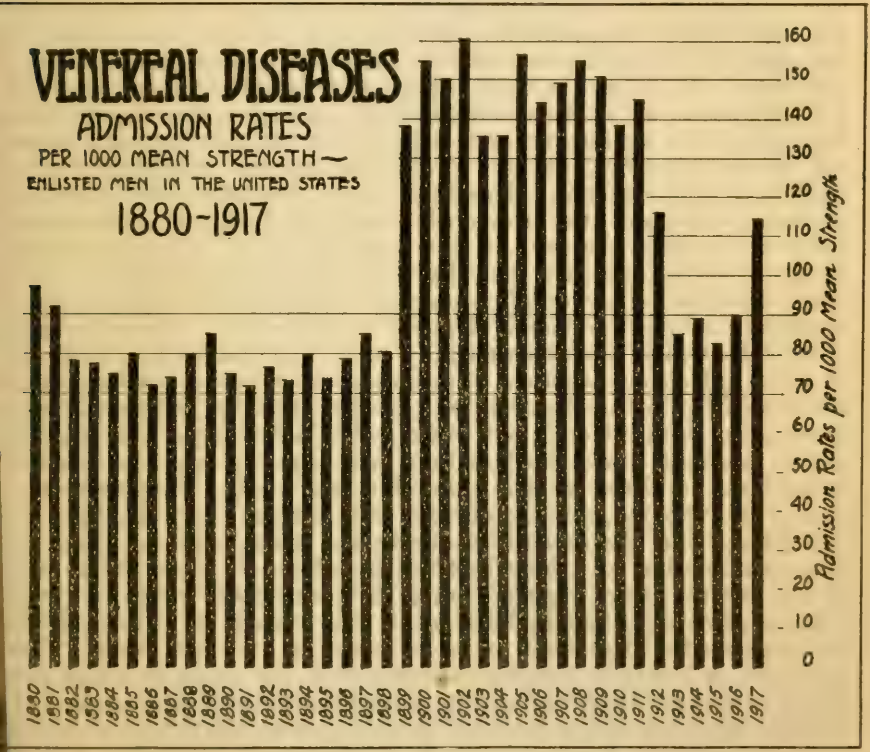

CHART NO. 61.

The admissions to sick report are made up of two dissimilar groups ombined. One group consists of the cases of venereal disease that re contracted by soldiers while they are soldiers. The soldiers, as whole, represent a group of men who after they entered the Army ere cured of any active symptoms of venereal disease they may ave had. Then, each Thursday night, those who during the past eek dave been admitted to sick report (practically all of those who cquire the disease) are counted and a report made of the number. uch counting is, consequently, only of the recently infected. This onstitutes the one group of the total of admissions. One may not onclude that the number of admissions of soldiers measures the mount of illicit sexual intercourse. The Government has provided in each town near a camp and at each camp dispensaries where each soldier who has been exposed to infection is required to go for antivenereal prophylactic treatment. The penalty for neglect of this requirement is of such a sort that many of the delinquents receive treatment. Moreover, by thorough repressive measures in 1917, the activity of prostitutes about Army camps and in near-by towns has been reduced to a minimum. In consequence of these measures, combined with careful instruction as to the importance of continence, severe muscular activity, inaccessibility of alcoholic drinks, and well-organized relaxation, the number of soldiers who weekly are admitted to sick report for venereal disease is often strikingly small.

The second group of those admitted to sick report for venereal disease comprises cases detected as men from civil life were undergoing physical examination. The number of such men who are examined in a single week may be very great, sometimes as many as 10,000. They have in their earlier years received neither the careful instruction as to the desirability of continence nor the facilities for prophylaxis against venereal disease, nor the aids toward repressing the sex instinct, nor the protection against designing women which the camp affords. These new Army recruits of the week are not men who have just previously been cured of any active symptoms of venereal disease; on the contrary, they often show evidence of acute gonorrhea that they may have acquired 1, 2, 3, 5, or even 10 weeks earlier, or of chronic gonorrhea which may have been acquired through the course of many earlier weeks. Also, the cases of syphilis which are detected may be of long standing. Now, all of these infections, whether of more recent or more remote origin, are brought into the examination together with the individuals who have never been infected, are examined in a few days, and perhaps within a single week the infections are reported and the infected individuals admitted to sick report for that week. They represent, it may be repeated, not the current infections of the week (like the first group) but the detections during the week, resulting from the first examination of a long infected population. That 10,000 men of the second group reported on in a week should reveal a larger number of cases of venereal disease in that week than 10,000 soldiers in camp do for that week is to be expected and it is found. For example, in the latest report at hand, over ten times as many new admissions were from the second group as from the first group. It is clear that one is not justified in saying that relatively ten times as many civilians become infected with venereal disease in a week as do men in camp. The proportion of men found infected at the entrance physical examination during a week tells nothing about weekly rate of infection of the civilian population. Not unless the civilian population should become subjected to the same scrutiny and discipline as the Army population may we know, as we do from the Army, what proportion of the civil population gets infected each week.

Still, again, we may not compare the numerical importance of venereal diseases with other diseases in the Army, such as pneumonia, measles, scarlet fever, etc., by comparing the total number weekly admitted to sick report of venereal diseases and of the other diseases. The reason is that while, as we have seen, most of the venereal disease that comes to sick report is that detected among recruits coming to physical examination, very little or practically none of the pneumonias, measles, or scarlet fever admitted to sick report in any week is detected in the physical examination. The reason is twofold: First, persons who have active symptoms of pneumonia, measles, and scarlet fever are apt to defer their entrainment for camp, and, secondly, since these diseases run a swift course, the chance of a person who comes to the physical examination being in course of one of these diseases is relatively small. On the other hand, a person with a venereal disease does not defer his entrainment on that account (his symptoms do not interfere with his traveling about), and since the disease is prolonged in its course the chance that a person may be examined while in course of a venereal disease is relatively great. Supposing, to make this clearer, that every drafted man had been once infected with a venereal disease and with measles and pneumonia and scarlet fever between 1 and 365 days of the time he presented himself for examination, and assume also that all came up, whether sick or well, there would then probably be ten times as many cases of venereal disease to report as of all the other diseases together; because the sum of the period of duration of the other three diseases is probably only about one-tenth of the average duration of the various venereal diseases. That vastly more cases of venereal disease should be detected at the physical examination than of pneumonia, measles, and scarlet fever tells nothing about the relative numerical importance of these diseases. If, now, we turn to the camp population, we find that at a time of year when measles, pneumonia, and scarlet fever are not common there were in the week ending August 30, 1918, nearly twice the number of measles and 5 per cent more of pneumonia than of new infections from all venereal diseases added together. And this week is fairly representative of a summer week, but in the winter the measles, pneumonia, and scarlet fever increase much more than the venereal diseases. It is then only because each venereal disease in civil life has such a relatively long duration and consequently the chance of examination in affected persons is relatively large and because venereal diseases do not interfere with entrainment that relatively so many cases of venereal diseases find their way to the sick record at times of draft increments.

Having now cleared the ground of certain fallacies we may proceed to constructive investigations as to the distribution of venereal disease in the Army and in the general population.

As stated above, we do not know for the civilian population (as for the military) the rate at which they become infected with venereal disease. We may, however, compare parts of the civil population by considering the proportion found infected at entrance into the service. This proportion is not exactly given in our statistics (in which the new infections are mixed with the cases discovered on entrance) but since, in times of great increments to camp, the dilution of the numbers derived from the civil population by those from soldiers is relatively little, we may neglect it and assume that the cases of venereal disease admitted to sick report during the period that a camp is being filled up are practically determined by (or proportioned to) the cases of venereal disease detected in the draft increments.

To get at the ratio: admission ÷ increments, a table of strength of increments of the Army in the United States, and indeed, of our three armies of 1917, was drawn up (Table 97). With these increments, are compared the admissions to sick report from gonorrhea. Gonorrhea is selected as the commonest and one of the most easily detected of the venereal diseases.

An inspection of this table shows that for each Army there was a period of rapid increase followed by a reduction in the monthly increase. This reduction is usually due to the fact that regiments or divisions were withdrawn from the United States, but in part is due to a reduction in recruiting, as in September and October, 1917 (Chart 9). If now we select those months when each Army was most rapidly increasing we shall have the desired increments to compare with the admission from venereal disease and Table 97 has been constructed in accordance with these principles. Using the ratios thus deduced we are in a position to answer various inquiries about the relative prevalence of venereal disease in the Army and in civil life.

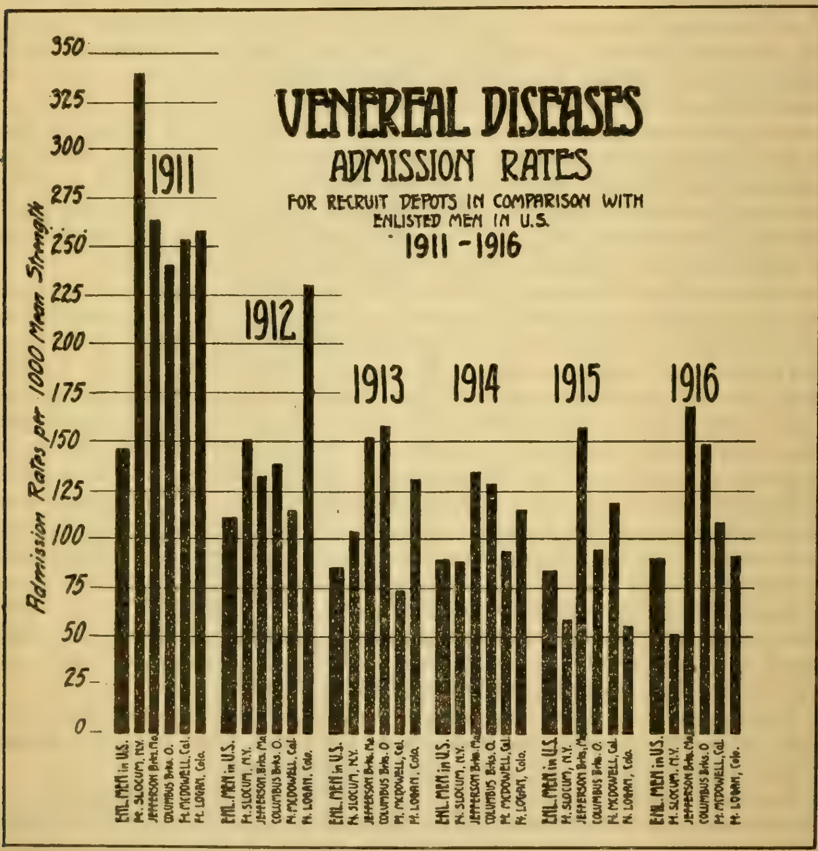

CHART No. 62.

4. IS VENEREAL DISEASE MORE OR LESS FREQUENT IN THE ARMY THAN IN CIVIL LIFE?

This is a frequent inquiry, but for reasons stated above it is impossible to give a precise answer. It appears from Table 109 that the most probable proportion of gonococcus infection in the males of draft age is between 2 and 3 per cent.

We may perhaps get a more precise estimate by dealing with the figures for the National Army alone. Up to the 31st of December about 465,000 enlisted men had been inducted into that Army, and there had been 12,351 admissions for gonorrhea in this Army. Assuming 11,000 of these cases have been detected at time of mobilization we have 2.37 per cent infected.[1] Since gonorrhea was not a cause of rejection by local boards or elsewhere, this would appear to give a fairly close estimate of the proportion of persons, age 21 to 31, in civil life who at a given time have obvious symptoms of gonorrhea. In camp the initial cases of gonorrhea have been cured. In consequence of Army ideals and restraint, and in consequence of Army medical prophylaxis, relatively few new infections are gained each week, and since cases of gonorrhea that do come to sick report are mostly cured in a few weeks, the number of current venereal diseases in the Army camps is remarkably small; and much less than the present components of the Army had before they were inducted into military service, and before they had undergone the medical cleaning up that accompanied that induction.

5. COMPARISON OF FREQUENCY OF GONORRHEA IN WHITE AND IN COLORED TROOPS.

It has already been shown that, using the total admission to sick report, there is about 2.5 times as much gonorrhea among colored as white recruits. This result may be tested by the method of ratio of admission for gonorrhea to increments of white and colored respectively.

Of the 465,000 National Army men who have been examined up to December, 1917, probably about 3.3 per cent were colored.[2] Of the 12,351 admissions for gonorrhea in this Army 6.55 per cent were for colored troops—almost exactly twice the rate for whites.

Again the mean strength of the American troops in the United States Army, December, 1917, is given as 1,450,462, and that of January, 1917, as 200,224. Consequently, there were admitted to the Army during 1917 at least 1,250,000 men, and, indeed, some thousands more—let us assume, for the sake of calculation, 1,300,000. Assuming that no man was admitted twice to sick report for venereal diseases of all sorts we would have 71,955 men admitted, or 55 persons out of every 1,000 troops so admitted (including old infections in recruits and new infections). Making similar assumptions for white troops we have, for 1,250,000 white men entering and remaining in the Army, 66,903 admissions to sick report for venereal diseases, or 53 white enlisted men admitted out of every 1,000 in the Army. Of colored troops we have 45,000 enlisted men 5,052 admissions to sick report for venereal disease, or 112 colored persons so admitted out of every 1,000 strength. Here, again, there are relatively twice as many colored as white recruits (and troops) admitted to sick report for venereal disease.

---

[1] At the time of physical examinations at camps, 2.23 per cent of the recruits were found to have gonorrhea, according to later statistics.

[2] The average enlisted strength of selected camps in the United States in December was 857,563, of whom 29,3 5 were colored, or 3.4 per cent. The Adjutant General gives for the whole Army in the United States a mean strength of 1,248,172 in December, of which 38,555 are colored, or 3.1 per cent.

6. RELATIVE AMOUNT OF VENEREAL DISEASE IN THE THREE ARMIES. IS THERE A DIFFERENCE IN THE INCIDENCE OF VENEREAL DISEASE IN THE REGULAR ARMY, THE NATIONAL GUARD, AND THE NATIONAL ARMY?

Considering the mean annual rate of venereal disease per 1,000 as given in Table 102, it appears that the rate for white troops is 114 for Regulars, 120 for the National Guard, and 90 for the National Army, and, among colored troops, 352 for the Regulars, 590 for the National Guard, and 213 for the National Army. In general, the annual admission rate is least in the National Army, greater in the Regulars, and greatest in the National Guard, in the ratio of 95:120:124.

This comparison of ratios is not altogether satisfactory in view of the fact that the armies grew at so very diverse rates; so that the diseases brought in by increments played a very diverse part. So a new table (Table 97) was made giving for the various armies the relation of admission to sick report for gonorrhea to increments of the armies, as shown (in part) in figures 10 to 39.

TABLE No. 97.—*Gonorrhea by increments.*

[1] See (in part) Report of the Adjutant General of the Army to the Secretary of War, Washington, 1917, Table B.

A study of Table 97 shows plainly that only certain selected portions of it can be used for our purpose. Thus, of the Regular Army, we can make use of only the months of April, May, June, and July. Later than that the increment is not significant, since troops were going overseas and the apparent increment in the United States is merely the difference between the additions by recruiting and the subtraction of the overseas troops. To divide the total number of admissions from gonorrhea by this difference tends to give an absurdly high figure. For similar reasons we take the National Guard figures for April to August inclusive only. For the National Army we take the period September to December, inclusive. On these assumptions we find in the Regular Army 3,483 admissions at a time when 157,000 recruits are being received, or 22 per 1,000 recruits. In the National Guard 5,010 admissions occurred at a time when 265,000 men were being enlisted, or 19 per 1,000. In the National Army 12,227 admissions at a time when 452,000 were being inducted into service, or 27 per 1,000 men. On this basis the relation of infection in increments of the National Guard, Regular Army, and National Army, is as 19:22:27.

Here again we reach the conclusion that the amount of active gonorrhea in our white civil population among men of age 20 to 35 is at one time only about 2 per cent.

We can reach a comparison of the proportion of venereal disease between volunteers (National Guard) and drafted men by comparing the ratio of admissions for gonorrhea to increments in the National Guard camps and in the National Army camps. This comparison is made in Table 98. In this comparison the drafted men show a higher incidence of venereal disease than volunteers in the ratio of 167 to 126 or as 4 to 3. Since the other comparison gives the relation of National Guard to National Army as about 5 to 3, it is probable that the facts lie between the two results or as 4.5 to 3 or 1.5 to 1. That is, the drafted men showed about one and one-half times more venereal disease than the volunteers. But it is to be recalled that a large part of the increments to the National Guard had previously seen service, had been cured of venereal disease and had the benefit of knowledge as to prevention and prophylaxis acquired in the Army.

7. RELATIVE FREQUENCY OF VENEREAL DISEASES IN RURAL VS. URBAN RECRUITS. ARE RECRUITS FROM THE CITIES MORE LARGELY INFECTED WITH VENEREAL DISEASE THAN THOSE FROM RURAL DISTRICTS?

Using method of admission to sick report in relation to increments, camps are first separated into two groups (*a*) the urban group, including camps that received troops from a population of high density (as shown in Chart 47) and (*b*) the rural group, of which the tributary population came from regions of low density. Furthermore, the National Army and National Guard camps are treated separately. Then the total admissions to sick report for gonorrhea from any group are divided by the total increments in that group. The ratio is expressed per 1,000. The results are that in National Army urban camps the rate of admission for gonorrhea is 10.2, in National Guard urban camps 8.5, all urban camps 9.7 per 1,000, of increment. On the other hand in National Army rural camps the rate is 21.5; in National Guard rural camps 14.4; in all rural camps, 18.3. That is, there is almost exactly twice the amount of gonorrhea among rural recruits that there is among urban recruits. The difference in racial constitution (white and colored) of urban and rural communities does not significantly influence this result.

Incidentally, this table reveals the excess of venereal disease in the increments to National Army over those to the National Guard camps that we have seen before. The ratio is about the same as before (124:159) although not all camps are included in both tables.

8. HOW DOES THE RATE FOR GONOCOCCUS INFECTION IN THE ARMY IN EUROPE COMPARE WITH THAT IN AMERICA?

Rumors have been spread of the great amount of venereal infection among our soldiers in France. Is there any justification for these rumors? The statistics give a mean annual admission rate for gonorrhea of 36.24 per 1,000 in Europe and 82.47 in the United States. Also among colored troops of 66.4 per 1,000 in Europe as compared with 203.04 per 1,000 in the United States. The figures are thus larger for troops in the United States than for troops in Europe. Conclusions may be drawn from this statistical result only with caution.

As we have seen above the admission rates for venereal disease in the United States troops contain the infections, often long standing, of recruits; while those of Europe comprise only current infections of men in the service. In our relatively stable Army of 1913 the mean annual rate for white enlisted men was 53.7, while that for colored enlisted men was 82.3. Both of these rates are greater than the corresponding rates for enlisted men in Europe, 1917. On the other hand the European rates exceed the midsummer rates of 1918 in the United States which are about 14 per 1,000.

Hyperopia	79		
Strabismus	15	Total	3,631

[1] Men held at camp a few days before discharged.

IV. CEREBROSPINAL MENINGITIS.

The data on meningitis were presented under the diagnostic terms: "Meningitis, cerebrospinal (epidemic)," and "meningitis, other than epidemic or tuberculous." The latter is distinguished as "simple."

1. SIMPLE MENINGITIS.

The following table gives the distribution of admissions, discharges and deaths, by Army, and by color, in the United States and Europe.

TABLE No. 111.—*Simple meningitis.*

	White.				Colored.				Total white and colored.
	Regulars.	National Guard.	National Army.	Total.	Regulars.	National Guard.	National Army.	Total.	
Admissions:									
United States	16	26	11	53			3	3	53
Europe	1	2		3					6
Discharges:									
United States	1	4		5					5
Europe									
Deaths:									
United States	5	10	7	22			1	1	23
Europe	1			1					1

Of the above cases of simple meningitis, 6 were complications of neasles, and of these 1 recovered and 5 died. One other is given as complication with mastoiditis, following otitis media; that also lied. Two others followed lobar pneumonia, in turn a complication f measles; they both died. Two others followed broncho-pneu- nonia, complicating measles; they also died. As complicating rimary lobar pneumonia, there were 12 cases, of which 1 recovered, 0 died, and 1 was remaining at the end of the year. Altogether, as he table shows, a large proportion of those who fell ill of simple neningitis died, namely, 24 out of 59 cases, or about 41 per cent.

istribution of admissions of cerebrospinal meningitis, Army in the United States, by States from which each National Army camp drew its troops. Charted in four grades. The darkest areas indicate greatest resistance to (least incidence of) the disease. The order of States, together with the limits of percentage of incidence of the disease represented in each grade of shading, is as follows: 1. 0–1: Dix, Upton, Devens, Custer, Grant. 2. 1.1–3.50: Lee, Meade, Sherman, Lewis, Gordon, Dodge, Travis, Taylor. 3. 3.50–3.75: Funston. 4. 3.75+: Pike, Jackson.

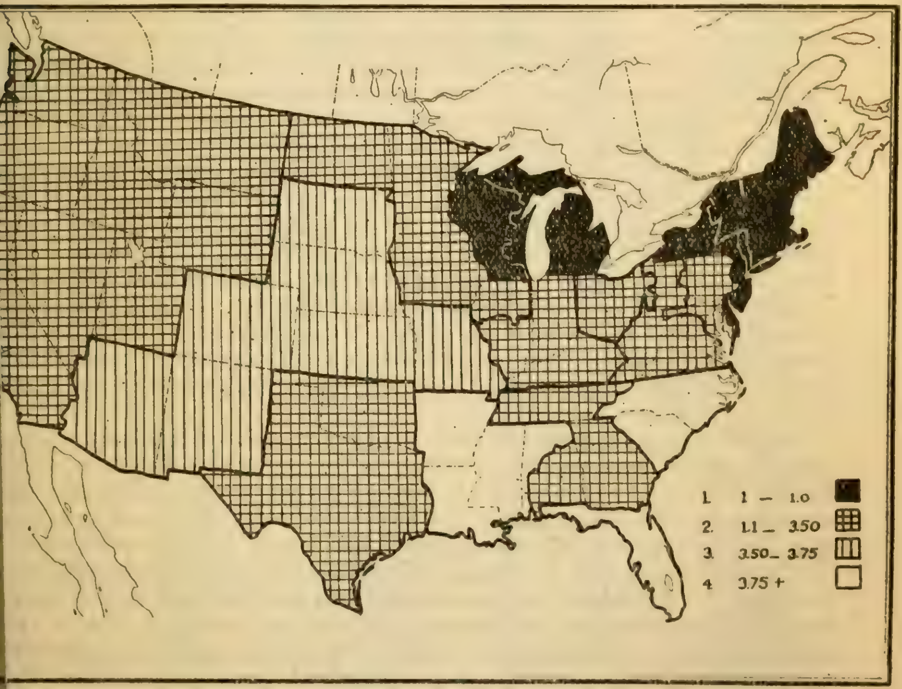

CHART No. 63.

2. EPIDEMIC CEREBROSPINAL MENINGITIS.

During the period of training soldiers in the United States in 1917 here were 971 admissions on account of cerebrospinal meningitis. addition, there were 66 cases in the Army in Europe. Of the 971 ses in the United States, 302, or 31.1 per cent, died; of the cases in urope, 19 died. Of all primary infectious diseases it had the highest ortality rate. Besides the cases of primary cerebrospinal meningitis here were 5 fatal cases in which it was complicated by broncho- eumonia; in 4 by lobar pneumonia and in 1 case by acute diffuse ritonitis.

3. EPIDEMIC MENINGITIS BY CAMPS.

Tables 52 and 54 give the statistics for cerebrospinal meningitis in the larger camps. There were 600 cases altogether, and only Camp Dix in New Jersey and MacArthur in Texas were free from the disease Several camps containing northern troops (Upton, N. Y., Mills, N. Y. Wadsworth, S. C., and Devens, Mass.) had only 1, 2, or 3 cases. On the other hand, certain camps had or were threatened with an epidemic of this dread disease. The severest outbreak was at Camp Jackson, S. C. There were in November 20 admissions of white patients and in December of 98 white and 8 colored. Of these 126 cases, 29 per cent died. For origin and history of the epidemic see the description of Camp Jackson (pages 78–81). The camp surgeon is inclined to think that a number of these cases were complications of measles.

The next most important outbreak was at Camp Beauregard, La. The first admissions were in early November and 3 to 5 were admitted each week until in the last week of December 28 cases were reported and then the epidemic gradually faded away. The mortality was 3 per cent to end of the year with a number remaining in the hospital By quarantine and search for carriers the epidemic was brought unde control. The next most serious outbreak was at Camp Funston, whos troops came from the Great Plains region, including a notorious meningitis center. The outbreak started in October with 16 admission during the month. There were 21 cases in November and then th disease practically disappeared. Of the cases, 11, or 29 per cent died. In Camp Pike the first cases of meningitis appeared in October. They were traced to a contingent that came from Camp Funston There were 32 cases in this camp and 7 deaths. The epidemic decreased toward the end of the year. It is interesting to note tha Camp Beauregard attributed the origin of its epidemic to a contingent from Camp Pike; hence the cases at Beauregard also traced bac to Camp Funston.

Of the above mentioned cases, a number were of the fulminatin type in which death occurred within half a day of the first symptoms Serum treatment was used with varying success. A striking circumstance is the fact that rarely did two cases come from one organization, indicating that the susceptible were rather sparsely scattered.

The distribution of the States of occurrence of meningitis patien is striking. Practically no cases came into the National Guard cam from the northern tier of States. It was the southern States tha supplied Camps Beauregard, Bowie, Doniphan, and Kearney wit their susceptible troops. As in the National Army camps, there we practically no cases from the northeastern States and few from an of the northern States. But immunity was much less common in th South and Southwest (Chart No. 63). Finally, if State of nativity i considered, it appears again that the northern tier of States have co tributed to the Army practically no sons who became victims of th cerebrospinal infection. The great home of the susceptible is n sparsely settled States, merely (for soldiers in Utah and Wyoming a practically immune), but natives of the Southeastern States (includin Kansas and Nebraska). It must be admitted that all of the factors d termining susceptibility of a population at 20 to 30 years are n known, but it is probable that the naturally susceptible are ea weeded out or immunized in the more densely settled regions.

TABLE No. 112.—*Complications with fatal cases of cerebrospinal meningitis epidemic, enlisted men in United States, 1917.*

Primary disease.	Complications.	Number of deaths.
Cerebrospinal meningitis, epidemic	Broncho-pneumonia Peritonitis, acute, diffuse Pneumonia, lobar	5 1 4
Total		10

Total admissions for cerebrospinal meningitis, epidemic 971
Total deaths for cerebrospinal meningitis, epidemic 302

V. SCARLET FEVER.

No epidemics of scarlet fever of any consequence occurred in 1917. Among the total admissions from all diseases those from scarlet fever ranked twenty-third in point of frequency and constituted only 0.4 per cent of the total admissions in the United States. As a cause of death it was somewhat more important in point of position, being seventh in rank, but only 1.61 per cent of the total deaths from disease are attributable to scarlet fever. The total number of days lost by the Army in hospitals or at quarters in the United States was 45,714 or 1.01 per cent of the total days lost from disease. As a cause of noneffectiveness it was exceeded by 20 diseases.

The following table gives the admission, discharges, and deaths due to scarlet fever by Army and by color in the United States and Europe.

TABLE No. 113.—*Scarlet fever.*

	White.				Colored.				Total white and colored.
	Regulars.	National Guard.	National Army.	Total.	Regulars.	National Guard.	National Army.	Total.	
Admissions:									
United States	1,042	494	419	1,955	3		8	11	1,966
Europe	52	107	8	167					167
Discharges:									
United States	3			3					3
Europe									
Deaths:									
United States	27	3	18	48					48
Europe	2	6		8					8

The number of cases is so small that the distribution by Army and by color is not to be regarded as very significant. As the above data stand, however, it will be seen that scarlet fever was much more frequent and fatal among the white than among the colored troops. Considerable differences exist in the relative frquency in the different armies. In the United States scarlet fever was twice as frequent among the Regulars as among either the National Guard or National Army, the rate per 1,000 being 5.37, 2.57, and 2.63 respectively. The death rate also was higher among Regulars being 0.14 per 1,000 in the Regular Army in contrast to 0.02 per 1,000 in the National Guard and 0.11 per 1,000 in the National Army.

On the other hand the ratios in the United States differ greatly from those in Europe. The rate of admission for the Regular Army drops from 5.37 per 1,000 in the United States to 1.51 per 1,000 in Europe while that for the National Guard increases from 2.57 to 11.26 per 1,000 and that for the National Army from 2.63 to 8.13 per 1,000. The rate for all armies is slightly higher in Europe (3.66 per 1,000) than in the United States (3.52 per 1,000). The changes in the death rates in the United States and in Europe for the different armies are similar to the changes in rate of admissions.

Distribution of admission to scarlet fever, Army in United States by States from which each National Army camp drew its troops. Charted in four grades. The darkest areas indicate greatest resistance to (least incidence of) the disease. The order of States, together with the limits of percentage of occurrence of the disease represented by each grade of shading, is as follows: 1.0–0.3. Gordon, Taylor, Lee, Jackson, Devens, Upton. 2. 0.3–1.0. Funston, Grant, Travis. 3. 1–5. Dix, Meade, Sherman, Custer, Dodge. 4 over 5. Pike, Lewis.

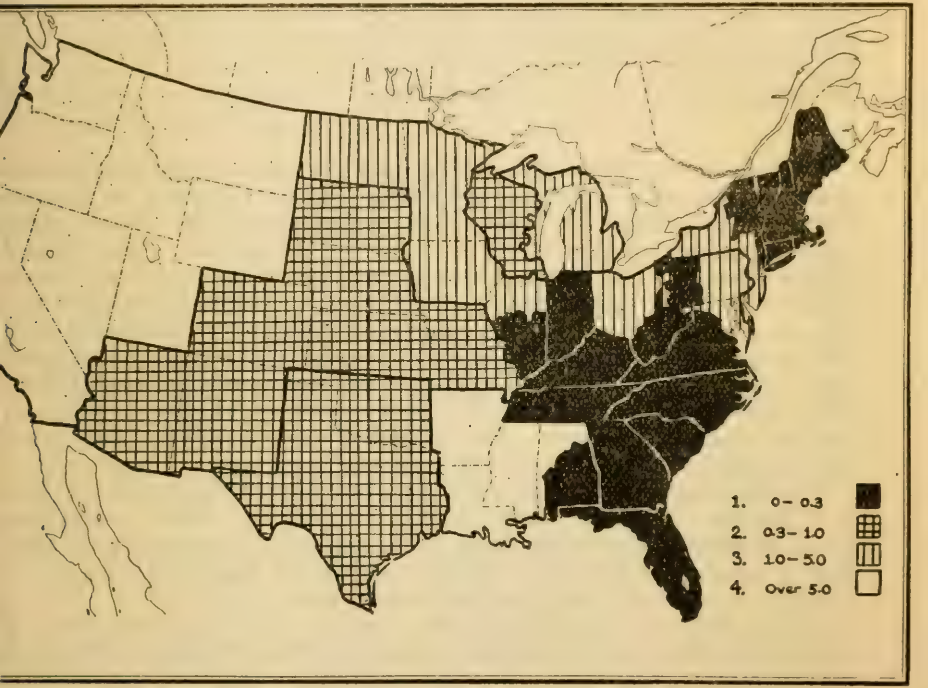

CHART NO. 65.

Below are tables showing the rate of admissions from scarlet fever per 1,000 mean strength in the National Army and National Guard camps.

TABLE No. 114.—*Scarlet fever by Camps.*

National Guard camps.	Rate per 1,000 mean strength.	National Army camps.	Rate per 1,000 mean strength.
MacArthur	6.66	Pike	34.26
Kearney	5.72	Lewis	8.67
Doniphan	3.94	Dodge	3.63
Cody	2.56	Custer	2.04
Greene	1.78	Sherman	1.67
McClellan	1.55	Meade	1.37
Sheridan	1.02	Dix	1.26
Wheeler	.35	Travis	.82
Bowie	.27	Grant	.43
Hancock	.23	Funston	.39
Logan	.22	Upton	.27
Shelby	.14	Devens	.24
Wadsworth	.11	Jackson	.12
Sevier	.00	Lee	.00
Beauregard	.00	Taylor	.00
		Gordon	.00

Only in camps Pike and Lewis, both National Army camps, did scarlet fever reach sufficient proportions to be regarded as an epidemic. Camp Pike leads all other camps strikingly. There were 111 admissions in November and 164 in December. The spread of the disease in this instance was in part due to its mild type, which rendered its diagnosis difficult, and in part due to inefficient quarantine measures. The men were quartered in squad rooms containing 120 men, which made it difficult to segregate the infected and exposed individuals. A small epidemic occurred also in Camp Lewis. Eleven admissions were recorded in November and 80 in December, but no deaths occurred. The spread of the disease in this camp was in part due to cross infection in the hospitals.

The distribution of scarlet fever by State of nativity has no obvious significance. However, the camps having the lowest admission rates quarter men coming from the more densely populated States. But a number of the more sparsely populated Southern States were among those having very low admission rates.

Scarlet fever as a primary cause was one of the lesser causes of deaths in 1917. As in the case of many other diseases, however, it served in many cases to lower the resistance of the patient to other and complicating disease, the various complications after proving fatal.

Of the 48 deaths attributable to scarlet fever in the United States 34 were complicated by other diseases as follows:

TABLE No. 115.—*Complications with fatal cases of scarlet fever.*

Complications.	Number of deaths.	Complications.	Number of deaths.
Epistaxis	1	Valvular heart disease mitral insufficiency	1
Lymphadenitis	1	Pneumonia, broncho	20
Myocarditis	1		
Nephritis, acute	2	Total	34
Pneumonia, lobar	8	Total deaths from scarlet fever	48

Here again broncho and lobar pneumonia are the most important complicating diseases.

VI. TUBERCULOSIS.

Though tuberculosis heads the list of causes of death by disease in the civilian population, in an Army that has been recently examined for it and from which it has been largely eliminated, naturally it will not be a disease of major importance. Yet, despite all precautions, there were in the United States troops during 1917, 7,274 admissions for tuberculosis of the lungs, giving a mean annual rate among whites of 12.52 and among colored of 33.92 (Table 116). Here, as elsewhere, the morbidity rate for tuberculosis is much higher among colored than white troops. The admission rate for white troops in Europe was relatively low in 1917, namely, 3.54. For some reason that is not quite clear the death rate of the National Guard was 50 per cent greater than that of the National Army; but this may be merely a statistical result, owing to the different ways in which the strength of the National Guard and the National Army respectively are distributed through the months.

	3	4	....	7	....	....	....	......	7

Tuberculosis constituted a cause of 4.1 per cent of all deaths from disease in the Army enlisted men in 1917. For the corresponding ages of life in the registration area of the United States tuberculosis constituted 34.7 per cent of all deaths. The contrast between 4.1 and 34.7 per cent indicates in a rough way the efficiency of the selective physical examination.

The number of admissions varied a good deal in soldiers born in the various States (Table 117). This is of course partly dependent upon the number of troops derived from the different States and partly upon the conditions (of the constitution of the population, or other) in each State. Assuming that the number of natives of each State is roughly proportioned to the male population, 20 to 29 years, census of 1890, the ratio of admissions to such male population has been calculated and the States arranged in order thereof (Table 117). There are a good many objections to this procedure (such as, that the quota going into the Army from the various States was not strictly proportioned to the population, etc.), but it constitutes a rough attempt to get rid of the varied strength of the Army from different States of birth.

The table indicates that the States with the high ratios for tuberculosis in the Army are: (1) Certain States of the Southwest much frequented by tubercular patients. Examples are: New Mexico, with the highest rate, 5.39 per 1,000;[1] Arizona, 3.20; California, 1.93; Colorado, 1.77. Probably Texas 2.29 and Florida 1.23 belong in this category. (2) Southern States, because they have a large proportion of colored people, have a much heavier death rate than northern. Here belong Alabama, 1.41; Mississippi, 1.35; and Georgia, 1.26. Some of the States with lowest percentage of deaths in the Army are Utah (not a refuge for tubercular patients); Montana, 0.38; and West Virginia, 0.64. Since the lowest rate is less than one-tenth the highest it is clear that constitution of the population and conditions in a State play a great rôle in determining the proportion of its sons that are admitted to sick report in the Army for tuberculosis. It is interesting to note that at the time of the last mortality census (1915) California and Colorado had high mortality rates and Utah the lowest of all. Thus the constitutional

Distribution of admissions to tuberculosis, Army in United States, by State of nativity of enlisted men. Charted in four grades. The darkest areas indicate the highest incidence of the disease. 1. 6-1.5, New Mexico, Arizona, Texas, California, Colorado, Tennessee. 2. 1.4-1.0, Illinois, New Hampshire, Idaho, Alabama, Kentucky, Mississippi, Arkansas, Georgia, Florida, Virginia, Missouri, Maine, North Carolina, Kansas, Wisconsin. 3. 099-0.60, Iowa, Oregon, Connecticut, South Carolina, Indiana, Louisiana, Michigan, Oklahoma, District of Columbia, Minnesota, Pennsylvania, Vermont, New York, North Dakota, West Virginia, Ohio, Massachusetts, New Jersey. 4. 0.59-0.25, Nebraska, Wyoming, Washington, Maryland, Rhode Island, South Dakota, Montana, Delaware, Utah.

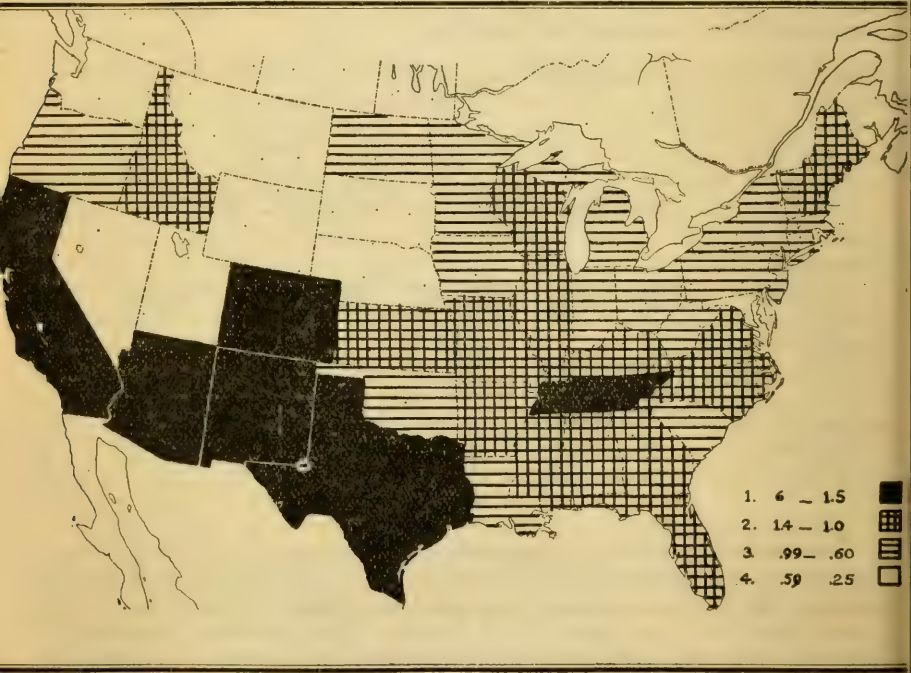

CHART NO. 66.

---

[1] These rates can not be used for comparison with rates in civil life. They are simply cases of tuberculosis born in the State divided by the male population in State, 20 to 29 years of age, 1890.

resistance to tuberculosis of the population of States is an attribute that persists for at least a generation.

The admission rate from tuberculosis varied greatly by camps in proportion to their mean strength. Thus Camp Kearney, Cal., led in this respect (Table 49). This is readily explained in view of the susceptibility of the men who are native to the States from which Camp Kearney draws, including New Mexico, Arizona, and California. These are States that stand first, second, and fourth, respectively, in mortality from tuberculosis in civil life. They are States which have long been resorted to by victims of chronic pulmonary tuberculosis. Their descendants probably carry a tubercular diathesis. Camp MacArthur, Tex., came second. This drew from Wisconsin and Michigan, States which have not an exceptional amount of tuberculosis. Among camps with a low rate of admission from tuberculosis were Upton, 11.15; Wadsworth, 7.18; and Dix, 8.82; which drew from prevailingly urban populations.

Total admissions for tuberculosis	7,274
Total deaths from tuberculosis	114

VII. MUMPS.

Mumps was one of the commonest of the infectious diseases prevailing in our Army camps in 1917. In fact, it was one of the very few diseases which reached greater proportions in 1917 than in the corresponding initial period of our Civil War. Among the enlisted men in the United States mumps was a cause for admission to the sick report in 21,725 cases, or 4.39 per cent of the total admissions were for mumps. Gonococcus infection, measles, diseases of the tonsils, bronchitis, and influenza were the only causes having higher rates. Among our troops in Europe mumps accounted for 11.03 per cent of the total admissions to the sick report, being outranked only by bronchitis and influenza.

For the most part, the mumps that occurred was of a mild type and few deaths resulted from it. The most frequent complication reported was orchitis. No discharges from any branch of the service were attributed to mumps.

The seriousness and importance of this otherwise relatively unimportant disease lie in the large number of days lost to the service on account of it. Among the enlisted men in the United States 5.62 per cent of the total number of days lost on account of disease were due to mumps. Measles and gonococcus infection alone were more serious from this point of view. Among our troops stationed in Europe mumps leads all other diseases as a cause of lost time and accounted for 13.57 per cent of the total number of days lost.

Below is a table showing the number of admissions and deaths due to mumps by armies and by color in the United States and Europe.

TABLE No. 121.—*Mumps, enlisted men, 1917.*

	White.				Colored.				Total, white and colored.
	Regular Army.	National Guard.	National Army.	Total.	Regular Army.	National Guard.	National Army.	Total.	
Admissions:									
United States	6,760	10,109	4,366	21,235	86	175	229	490	21,725
Europe	1,887	1,373	72	3,332	415				3,747
Deaths:									
United States	1	3	3	7	1			1	8
Europe		1		1					1

The above table of admissions becomes more significant if we substitute the ratio per 1,000 men for the absolute numbers.

Distribution of admissions to mumps, Army in United States, by State of nativity of enlisted men. Charted in four grades. The darkest areas indicate greatest resistance to (least incidence of) the disease. The order of States, together with the limits of percentage of incidence of the disease represented by each grade of shading, is as follows: 1. 0.6, R. I., N. Y., N. J., Conn., N. H., Mass., Pa., Nev., Md., D. C., Me., Del. 2. 0.6–1.0, Mont., Cal., Wash., Ohio, Ill., Colo., Ariz., N. Mex., Vt., Minn., Wis., N. Dak. Wyo., S. CHART No. 67.

TABLE No. 122.—*Ratio of admissions for mumps.*

	White.				Colored.				Total, white and colored.
	Regular Army.	National Guard.	National Army.	Total.	Regular Army.	National Guard.	National Army.	Total.	
United States........	34.85	52.64	27.37	38.93	16.31	121.11	35.60	37.26	38.89
Europe...............	54.79	144.45	73.17	74.16	574.00	....	....	....	82.08

Considering first the distribution by Army, it will be seen that both in the United States and in Europe, among the colored as well as the white troops, mumps was much more prevalent in the National Guard than in either the Regular or National Armies.

The above tables show us that mumps was twice as prevalent among our troops in Europe as among those in the United States. This increase prevailed in all three armies and among both colored and white troops.

As mentioned before, very few deaths resulted from mumps. A total of nine deaths resulted from 25,472 admissions. The death rate was consistently greater in Europe (0.02 per 1,000) than in the United States (0.01 per 1,000).

It may prove of interest to treat in some detail the distribution of mumps by camps of occurrence and State of nativity of the victims of mumps in the United States. Following is a table of the rate of admissions per 1,000 mean strength in the National Army and National Guard camps.

TABLE No. 123.—*Admissions per 1.000 mean strength, by camps.*

National Army camps.	Rate per 1,000.	National Guard camps.	Rate per 1,000.
Lee	163.8	Beauregard	454.9
Travis	156.3	Wheeler	390.4
Jackson	64.1	Bowie	205.5
Pike	55.4	Shelby	108.3
Custer	38.4	Sevier	68.6
Dodge	29.3	Greene	41.2
Taylor	16.5	Kearney	23.1
Grant	13.6	MacArthur	18.7
Lewis	13.1	Sheridan	10.3
Sherman	9.6	Logan	9.1
Upton	8.2	McClellan	8.3
Meade	7.5	Doniphan	7.3
Gordon	7.3	Cody	5.8
Funston	6.5	Hancock	4.4
Dix	2.4	Wadsworth	1.1
Devens	2.3		

This table serves to emphasize the difference in the rates for National Guard and National Army camps. The rates in the National Guard camps are considerably higher. However, in both armies mumps reached epidemic proportions in several camps. Camps Beauregard, Wheeler, Bowie, and Shelby have the highest rates of admissions among the National Guard camps while Camps Lee, Travis, Jackson, and Pike have the highest rates among the National Army camps.

Some idea of the size and duration of the epidemic in these camps may be gained from the following list of admissions taken from the monthly reports.

TABLE No. 124.—*Admissions, National Guard and National Army.*

	September.	October.	November.	December.
NATIONAL GUARD.				
Camp Beauregard	2	32	466	1,299
Camp Wheeler	6	17	301	1,923
Camp Bowie	14	111	342	1,035
Camp Shelby	1	66	331	383
NATIONAL ARMY.				
Camp Lee	1	7	276	990
Camp Travis	3	45	338	943
Camp Jackson	24	53	82	358
Camp Pike	4	1	123	344

It is very noticeable from the above table that the numbers of admissions in all of these camps increased appreciably from month to month and reached their maximum frequency in December.

In this respect the epidemics of mumps differ somewhat from the epidemics of measles which almost invariably reached their maximum in November and were well under control in December. Mumps on the other hand ran well over into January before being checked.

The above eight camps having the highest admission rates for mumps, all quartered troops coming from sparsely settled and rural regions. With the exception of Camp Lee they received very few troops from the larger towns and cities. Perhaps somewhat more than a third of the troops in Camp Lee came from the larger towns and cities.

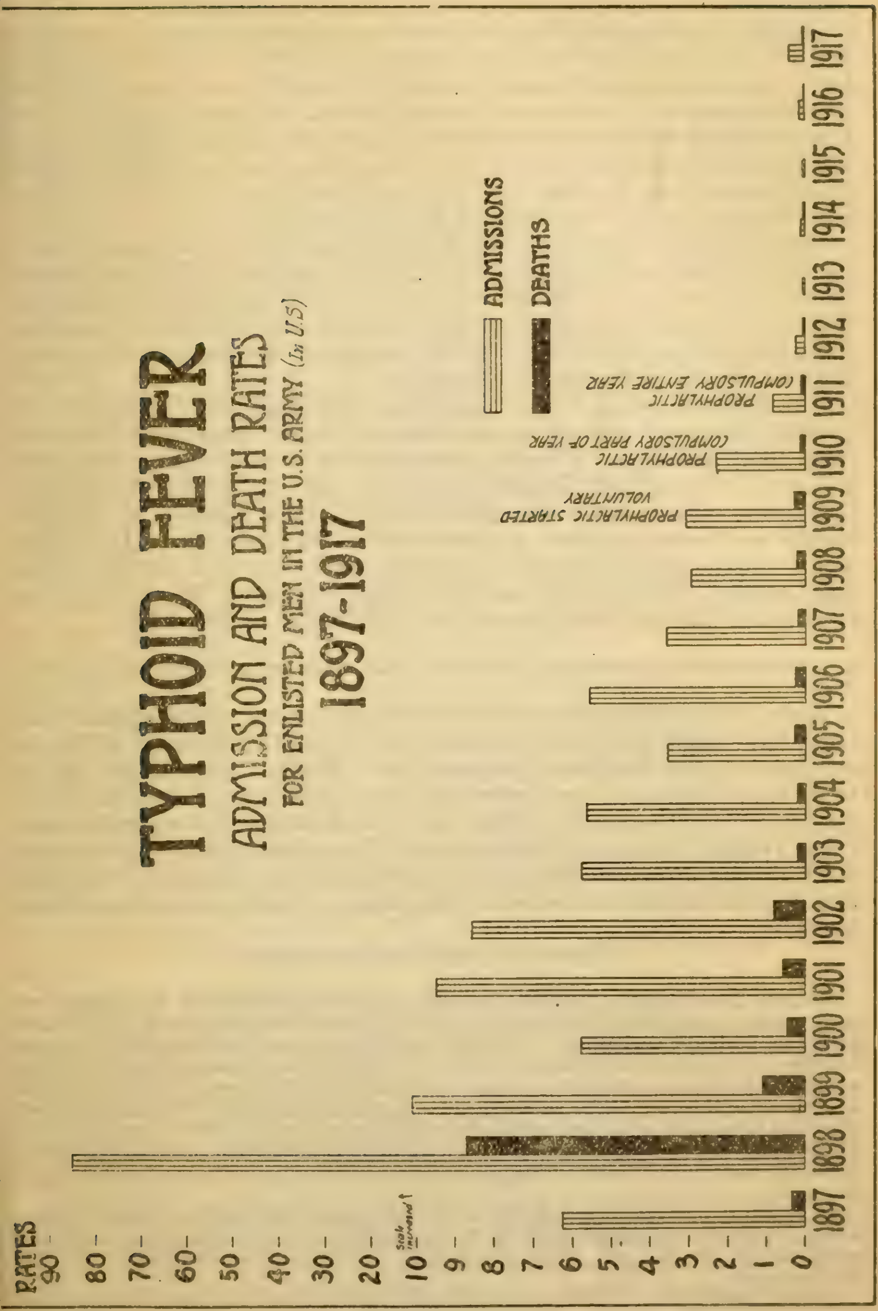
On the other hand, the camps showing the greatest immunity from mumps received men from the more densely populated areas. Among these are Camps Dix, Devens, Meade, and Upton of the National Army and Camps Wadsworth, Hancock, McClellan, Logan, and Sheridan of the National Guard. In other words, we find a distribution for mumps very similar to that noted for measles. Being also an infectious disease it seems reasonable to urge the same causative factor of immunity for mumps that was suggested for measles. In the cities mumps are so widespread that practically every child suffers an attack at or before his early school years and consequently grows up immune to mumps. But, on the other hand, in sparsely settled areas many individuals grow to adult life without having become immunized to the disease. The fact that we have at the one extreme a very high rate of admission among troops born in the rural States of Georgia, Alabama, Mississippi, Florida, Virginia, Arkansas, Texas, Kentucky, Tennessee, Kansas, Nebraska, and Oklahoma while at the other extreme we have an apparent immunity among the troops coming from the more densely populated States of Rhode Island, New York, New Jersey, Connecticut, Massachusetts, Pennsylvania, Maryland, Delaware, and District of Columbia seems to indicate that in the case of mumps also the early acquisition of immunity through crowding is an important factor in determining the rate of mumps in the camps. Crowding in camp quarters or in hospitals have also undoubtedly tended to facilitate the spread of the disease among those who were not already immune.

VIII. Typhoid Fever.

1. GENERAL.

Since 1911 the Surgeon General's reports have each year presented an increasing amount of convincing evidence of the value to the Army of compulsory antityphoid inoculation. In 1917 this method of protection was of course tested on a much greater scale than ever before, but the results have justified the previous conclusions as to its value. Substantial protection has been secured not only against typhoid, but also against paratyphoid A and B by use of the triple typhoid vaccine adopted soon after the declaration of war.

It will be noted in the statistical part of this report that during the year 1917 there were 297 cases of typhoid; 13 cases of paratyphoid A; 7 cases of paratyphoid B. A large proportion of the cases occurring in this country were in men who were in the incubation period of the disease on their entrance into the military service. The reports



TYPHOID FEVER
ADMISSION AND DEATH RATES
FOR ENLISTED MEN IN THE U.S. ARMY (In U.S.)
1897-1917

CHART NO. 68.

of the cases which occurred in France indicate that almost all the patients had escaped receiving the typhoid prophylactic.

During the Spanish War of 1898 the admission rate for typhoid was 141 per 1,000 and the death rate 14 per 1,000. If this experience had been repeated in this war, for each 1,000,000 men there would be 140,000 cases of typhoid and 14,000 deaths. It can not be claimed that all of our protection from such a calamity is due to vaccination, as sanitation had much effect, but enough cases are occurring in spite of all precautions to show that there is constant danger of infection and constant need of protection by vaccination.

Recent experiments conducted at the Army Medical School have resulted in the perfecting of an oil vaccine modeled after the French vaccine, by which a complete immunization can be given in one dose. This is a distinct practical advance as an administrative measure, as it saves time and labor. A full report of the work of the Army Medical School is presented elsewhere.

Examination of all food carriers has been made for carriers of the typhoid group of organisms, and carriers found have been excluded from food handling. Where possible these carriers have been sent to the Walter Reed General Hospital for study and treatment. One cook whose urine was practically a pure culture of typhoid bacilli was found to have a pyonephrosis on one side. His kidney was removed and he made a complete recovery as a carrier. Two gall-bladder typhoid carriers have been operated on for cure by removal of the gall bladder and are still under observation.

2. VACCINATION AGAINST TYPHOID AND THE PARATYPHOID FEVERS.

Since the mobilization on the Mexican border, paratyphoid vaccines have been used in addition to the typhoid vaccine for all troops on duty in the Southern Department. When troops began to go to Europe they, too, were given the para-vaccines. After the 1st of August, 1917, the two vaccines were combined and were given as a triple typhoid vaccine on one course of three doses, since experimental work during June and July had shown that the reaction, both local and general, was no more severe than that occurring after the typhoid alone.

3. REPORTS FROM DEPARTMENTS.

Southern Department.—With the prompt routine administration of typhoid and paratyphoid prophylaxis the number of cases of these infections among the military personnel is almost negligible. But four of each are reported from the regular service and three of typhoid in the National Army. There have been cases among the civilian employees who have not had the proper vaccination, but the present rate among those who have had the vaccination shows an almost perfect immunity. With such a record, when the large number of new recruits handled is considered, it would seem that with proper enforcement of suitable vaccination regulations outside the Army as well inside, these diseases might almost within a comparatively short time be rendered things of the past.

In regard to one case of death due to typhoid among the militia during the year, when no cases of typhoid are reported in the admissions for that disease, note that this was a case admitted in 1916, which died January 15, 1917, and is consequently included in this report.

Central Department.—There were 5 cases of typhoid fever, 2 of these being at Fort Leavenworth, Kans., and 1 at each of the following posts: Fort Benjamin Harrison, Ind.; Fort Crook, Nebr.; and Fort Riley, Kans.

The records show that the two soldiers at Fort Leavenworth, Kans., had completed typhoid inoculations; that the case at Fort Benjamin Harrison had been last immunized about the year 1912; that the case at Fort Crook had not been immunized; that the case at Fort Riley had received first dose only toward immunization prior to attack.

In addition to the above, Fort Leavenworth reports three cases of typhoid fever among civilians with no records of inoculation, their respective ages being 6, 16, and 20 years.

No typical cases of typhoid or paratyphoid reported. During the year, 16,075 cases have been immunized with excellent results and practically no serious reactions. Number at present not immunized, 217. These are new recruits and inoculations are now being given.

Western Department.—There have been eight cases of typhoid fever and one of paratyphoid in the command during the past year. In each case the medical officer was called upon for special report, required by instructions from the Surgeon General's Office. These reports indicated that either immunization had not been completed or that the soldier had acquired the infection prior to enlistment. Delay in immunization was apparently due to the rapidity with which it was necessary to move recruits from depots to regiments.

Eastern Department.—During August, five cases of typhoid fever were reported in the Fifth New Jersey Infantry stationed at Pompton Lakes, N. J. The surgeon of the regiment stated that there was considerable pollution of the ground by men defecating and urinating outside the latrines. On account of broken pipes connected with the toilet in a pumping station, discharges from the toilet entered a near-by well. This was proven by an aniline test. The records in regard to inoculation against typhoid were not properly kept, and it was found that there were large numbers in nearly all the companies who had not had the typhoid vaccination completed. This carelessness no doubt, accounts for the epidemic of typhoid in this organization.

One case of typhoid occurred in the Forty-seventh New York Infantry while at Lynchburg, Va., in September. The soldier had received one inoculation against typhoid in July, 1917.

One case of typhoid occurred at Grove Hill, Va., in a detachment of the Second Virginia Infantry on guard duty at that place. Typhoid existed outside of the camp in the section from which the milk supplied to the detachment came, but the source of the infection could not be definitely determined.

On August 27, in Companies C and L, First Virginia Infantry, at Lynchburg, Va., 75 out of 212 men were sick. Twenty-five of these had a temperature no higher than 99 degrees and little or no toxemia. The remaining 50 had temperatures of 100 degrees or more. Ten of the 25 mildly sick developed more severe symptoms and had to be confined to bed in the following 48 hours. The surgeon reported that the symptoms in these cases suggested typhoid, "if typhoid, was modified by vaccination." One case, sick three weeks in hospital, was reported to have a true clinical typhoid, but one of the State bacteriologists stated with regard to blood cultures in this case that he had obtained an organism "probable typhoid bacillus" but he could not satisfactorily identify it and on a second culture being obtained he was unable to find the organism. He secured 15 blood cultures from soldiers of this organization in hospitals but could find no evidence of typhoid. He remarked, however, that the media and the containers were unsatisfactory, the cultures being contaminated. The soldier who had clinical symptoms of typhoid had received only one vaccination against typhoid.

Two cases of typhoid were reported in the First Maryland Infantry during August, and one case in the Maryland Coast Artillery about the same time.

The surgeon, Fort Jay, N. Y., reported one case of typhoid fever admitted to the hospital September 4, 1917, and stated that the source of infection is unknown, probably contracted in a civilian community.

One case appeared at the camp of the Twelfth Field Artillery while stationed near Fort Myer, Va., and was sent to the post hospital, Fort Myer, Va., for treatment on October 7, 1917. The patient had recently been transferred from mobilization camp at Syracuse, N. Y., and his typhoid inoculation was completed at the encampment of the Twelfth Field Artillery on September 11, 1917.

At Fort Myer, Va., one case of typhoid in a candidate at the officers' training camp was admitted to the hospital August 23, 1917, the same day that he arrived, showing that the disease was contracted elsewhere.

Fort Oglethorpe, Ga.—During the summer and early autumn 43 cases of typhoid fever occurred. Of these 22 cases were part of an epidemic among German war prisoners as a result of eating contaminated cheese. Most of the Germans were vaccinated. This matter is covered by a special report forwarded to the Surgeon General.

4. HAWAII.

Since the epidemic of typhoid fever recorded in the report of 1916, there have been a few scattered cases at Schofield Barracks. Two of these are recorded in the report for 1917. For two years previous to October, 1915, when the small epidemic mentioned in the 1916 report occurred, there were no cases of typhoid fever. The 13 cases occurring in 1915 and 1916 developed in the following order: Six in October, 3 in November, 1 in December, 1915: 2 in January, and 1 in February, 1916. Of the 13 cases, 6 were Japanese, 5 were soldiers, 1 was an officer's son, and 1 was a white civilian employee. There was only one death, and that in an uninoculated Japanese. The noteworthy feature of the small epidemic in October, 1915, was the fact that all cases used the Koolau water supply. One of the cases, developing in the latter part of the epidemic, was taken sick at a camp of the constructing quartermaster, located on this water supply. The fact that this case occurred on the water supply and at a later date than the other cases rather tends to support the theory that the five other cases in this epidemic may have been due to one common source of infection, and that on the watershed. The opportunity for a carrier to infect this water supply by walking in the water, was present in 1915; but at this time there was no water going to the post except through a system of tunnels into which no water from the general drainage area occupied by human beings found its way. Toward the end of September, 1917, an epidemic of typhoid fever occurred in Schofield Barracks. The first cases were positively diagnosed on the 8th of October in two quartermaster employees. The first case reported to medical officers with symptoms and later diagnosed as typhoid fever was taken ill on the 23d of September. From then until January 17, 1917, 55 soldiers and 56 civilians contracted this disease. The last 11 cases, occcurring in civilians, were in unprotected persons, and from the nature and time of their occurrence were in all probability contact infections. During the period immediately preceding this epidemic, that is from the middle of August until the middle of September, there had been little heavy rainfall on the watershed and there was a large amount of construction on the water system with no reserve supply of water. Therefore, it had been found necessary, in order to keep up the flow of water, to use the accessory pumping station mentioned in the 1916 report more or less constantly, although the sanitary authorities did not realize that this was being done. It developed that, in the early part of August, a Japanese arrived at one of the camps of the laborers on the watershed, afflicted with a disease the symptoms of which indicated a typhoid-like condition, although the man himself was not located. While he was sick, a Japanese laborer, Mizusawa, in another camp designated "No. 2," visited him and Mizusawa was taken sick with typhoid fever during the last week in August. He continued to work for several days afrer the beginning of his illness and lived at Camp No. 2. He stopped work on the 1st of September, but continued at the camp until September 7 and arrived at Honolulu on the 10th, where he presented himself for admission to a hospital. His symptoms on admission were those of hemorrhage into the intestine and his blood showed a positive Widal reaction. In

October his blood still agglutinated the typhoid bacillus in high dilution. This man used an unsanitary privy at Camp No. 2, located on the drainage area of the stream which supplied the pool at the so-called "east pumping station," supplying water to the Castner section of Schofield Barracks. On the 13th and 14th of September, during this comparatively dry period, rather heavy rains occurred on the watershed, sufficient to cause the supply at Castner to become exceedingly muddy, as noticed at the faucets in the post. Ten days after the occurrence of this heavy rain the first cases of typhoid developed, and within a comparatively short period 100 cases had occurred. All of the cases at some time during the incubation period drank water from the Koolau supply.

The vaccinated population of the Castner section, supplied by water from the Koolau Range at the time of the epidemic, was 4,087; the unvaccinated population, 812. The following table shows the incidence and mortality in these two groups:

	Population on Castner water supply.	Number of cases of typhoid.	Cases per 1,000.	Deaths.		Mortality rate per 1,000.
				Number	Per cent.	
Vaccinated	4,087	55	13.45	4	7.4	0.97
Unvaccinated	812	45	55.41	7	15.5	8.62

This table indicates very clearly the protection afforded by the prophylactic and shows that whereas it is the most important factor in the elimination of typhoid fever from the Army, it can not be considered an absolute and never-failing protection and that all of the safeguards of general sanitation and personal hygiene must be preserved unimpaired. It is the first time in the history of prophylactic vaccination against typhoid in the United States Army that it has been possible to see the protection afforded by the prophylactic against water-borne infection. It is noteworthy that, all proper protective measures being used, the epidemic promptly ceased in the protected population, whereas 11 secondary cases occurred among those not vaccinated.

The investigation of this epidemic was made by a board appointed by the department commander. In addition to this board, the commanding officer of Schofield Barracks detailed a board. Both boards arrived at essentially the same conclusions in regard to the origin of the epidemic. In the report of the board first mentioned, the inadequacy of the present water supply, with its attendant conditions, namely, employees residing on the watershed and the necessity of using the pumping station whose source of supply came from a region polluted by human excreta, was considered as the essential contributory cause, and both boards also recommended the chemical treatment of all water from this watershed during the construction period and the treatment of all water during any time in which it became necessary to use the pumping station.

[1] Number of cases calculated by subtracting from gross number of admissions the remaining 1917 cases and the readmissions 1917.

TABLE No. 134.—*Case mortality rates from selected diseases. United States enlisted men, 1917.*

Diseases.	Cases.[1]	Deaths.	Case mortality rate, per cent of cases.
Apoplexy	19	13	68.42
Cerebrospinal meningitis (epidemic)	577	302	52.34
Septicemia	45	23	51.11
Meningitis, not epidemic	48	23	47.92
Broncho-pneumonia	1,066	202	18.95
Diabetes, mellitus	86	16	18.60
Cancer and other malignant tumor	75	13	17.33
Lobar pneumonia	4,912	747	15.21
Typhoid fever	192	18	9.38
Nephritis, acute and chronic	597	41	6.87
Peritonitis, acute and chronic	209	12	5.74
Scarlet fever	1,428	48	3.36
Measles	41,502	947	2.28
Alcoholism	1,470	29	1.97
Tuberculosis	6,027	114	1.89
Appendicitis	4,890	74	1.51
Organic diseases of the heart	3,163	47	1.49
Diphtheria and results	1,004	12	1.20
Pleurisy	2,662	11	.41
Otitis media	5,087	14	.28
Syphilis (all)	7,485	20	.27
German measles	7,616	17	.22

[1] Number of cases calculated by subtracting from gross number of admissions the remaining 1917 cases and the readmissions, 1917.

IX. THE FRUITS OF PREVENTIVE MEDICINE.

The crowding together in barracks of raw recruits many of whom come from sparsely settled areas is a procedure that is always fraught with great danger, a danger greater even than that of actual battle. Thus, it was stated by Virchow, in 1879, that in the Crimean War the French Army lost 96,615 men by death; only 10,240 fell before the enemy; about an equal number of wounded died in hospitals; and more than 75,000 men died of disease. In the American Civil War, 97,000 men died in battle and 184,000 from epidemics and sicknesses. Microorganisms are an enemy more to be dreaded in war than armed forces.

To understand the nature of the dangers that accompany the mobilization of an army it may be instructive to compare the annual number of deaths from various causes and the percentage that each is of the total deaths among males, 20 to 30 years of age, in civil life (1915) and in the Army enlisted men of the United States, white and colored (1917). Such a comparison is made in Table 135.

Table No. 135.—*Causes of sickness in Army and civil life compared.*

	Frequency.		Percentage of all deaths.	
	Civil.	United States Army.	Civil.	United States Army.
Age, years	[1] 20–29	21–30	....	....
Total annual deaths, all causes	3,093	3,611	....	....
	Average for year 1917.			
	Each year of age.	All ages.		
Typhoid fever (No. 881)	126.7	18	4.11	0.50
Measles (No. 477)	3.7	947	.12	26.23
Scarlet fever (No. 767)	4.2	48	.14	1.33
Diphtheria (No. 221)	8.8	12	.29	.33
Tuberculosis (Nos. 864–874)	1,062.8	114	34.36	3.16
Syphilis (Nos. 828–830)	16.4	20	.53	.55
Cancer and other malignant tumors	35.3	13	1.14	.36
Acute articular rheumatism, rheumatic fever (No. 745)	13.7	5	.44	.14
Diabetes (Nos. 212–213.)	32.4	16	1.05	.44
Alcoholism, acute (No. 029)	17.7	11	.57	.30
Meningitis (No. 482)	17.5	302	.57	8.36
Apoplexy (No. 064)	17.6	13	.57	.36
Epilepsy (No. 261)	26.8	6	.87	.17
Acute endocarditis (No. 247)	25.7	3	.83	.08
Valvular heart disease, mitral insufficiency only	129.0	7	4.17	.19
Broncho-pneumonia (No. 934)	18.6	202	.60	5.59
Lobar pneumonia (No. 620)	163.2	747	5.28	20.69
Pleurisy (Nos. 665–667)	9.7	11	.31	.30
Ulcer of stomach (No. 889)	14.5	7	.47	.19
Diarrhea and enteritis, over 2 years (Nos. 215–216–252)	12.8	2	.41	.06
Appendicitis and typhlitis (No. 065)	91.1	74	2.95	2.05
Hernia (No. 354)	3.6	5	.12	.14
Intestinal obstruction (Nos. 296–398)	12.7	10	.41	.28
Cirrhosis of liver (Nos. 447–448)	10.1	3	.33	.08
Simple peritonitis (Nos. 645–646)	5.6	6	.18	.17
Acute nephritis (No. 525)	25.5	15	.81	.42
Bright's disease (No. 526–527)	78.3	26	2.54	.72
Total deaths from traumatism	851.2	627	27.50	17.36
Total deaths from traumatism except military agents and air machines	....	405	....	11.22
Suicide (T 79)	132.2	109	4.28	3.02
Deaths from traumatism by crushing	237.9	116	7.70	3.21

[1] Average.

NOTE.—The terms used in naming causes of death in civil life are as given in United States Census Mortality Statistics, 1915, Table 7 A. The corresponding terms used for the Army data are indicated by numbers (in parentheses) which are those used in the "Coding Book for Diseases and Traumatisms," Medical Department, United States Army, 1917.

Table 135 shows the relative frequency of the various causes of death in civil life and in the Army. It seeks to answer such questions as this: Was measles (in 1917) a relatively commoner cause of death in the Army than in civil life? Is suicide a relatively commoner cause of death in the Army than in civil life?

To make a comparison between the Army and civil life, it has to be kept in mind that the Army consists chiefly of males between the ages of 21 to 30, inclusive. The census returns for mortality (of the registration area), 1915, give the number of deaths for each disease for all males, 20 to 29 years. There were 30,929 such deaths, or, on the average, 3,093 for each age year. This is to be compared with the 3,611 deaths occurring in the Army, 1917. To make the comparison more precise there is also given the percentage that each cause of death is of total deaths in civil life and in the Army, respectively.

Certain conclusions readily flow from this table. All causes of death may be classified in the groups, (1) much commoner in the Army than in civil life; (2) much less common in the Army than in civil life; (3) of nearly equal commonness in the Army and in civil life.

To the group of causes of death that are commoner in the Army than in civil life belong the following: Measles, 219 times relatively more important in Army than in civil life; meningitis, 14.7; scarlet fever, 9.5; broncho-pneumonia, 9.3; lobar pneumonia, 3.9.

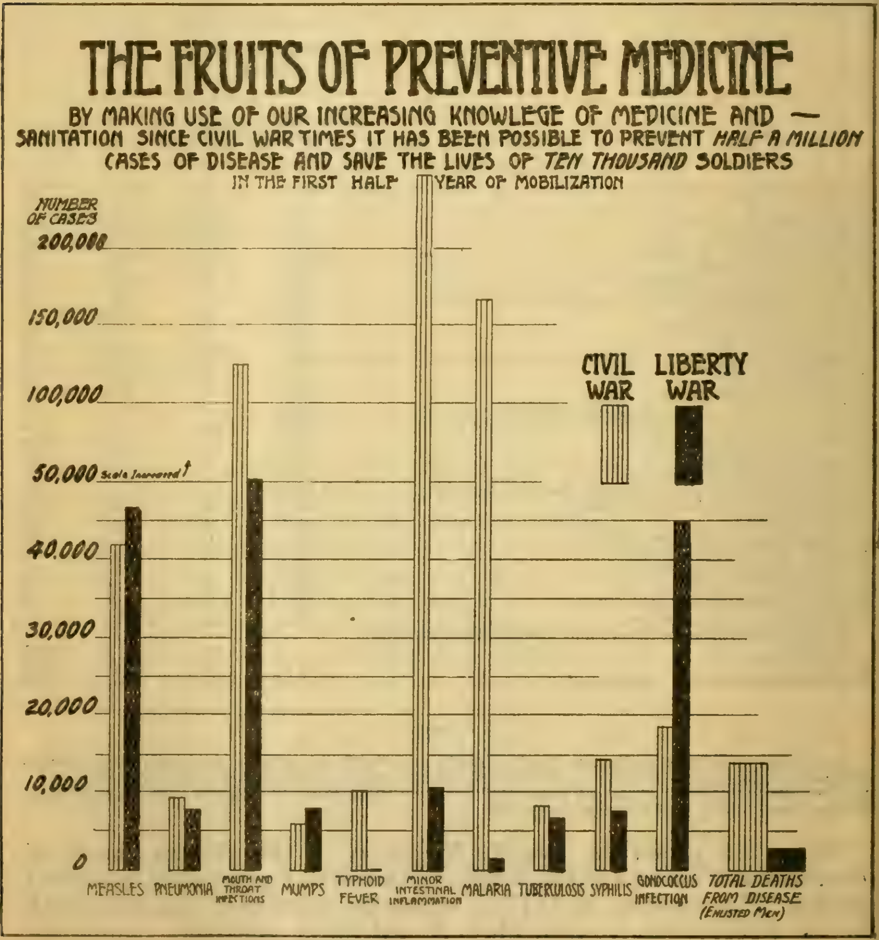

CHART No. 19.

In this group the diseases are characterized by their communicableness. The hypothesis suggests itself that their high death rate in the Army is due to the crowding of men at the cantonments.

To the group of diseases much less common in Army than in civil life belong: (Class I) Tuberculosis, cancer, epilepsy, acute endocarditis, organic diseases of the heart; (Class II) typhoid fever, diarrhoea, and enteritis, traumatisms; (Class III) diabetes, alcoholism, cirrhosis of liver, intestinal obstruction, hernia, rheumatic fever, ulcer of the stomach, Bright's disease.

The rate of Class I is low in the Army because liability to these diseases is selected against at the time of physical examination. Class II is low because of superior protective public sanitation in the Army. Class III is low chiefly because of superiority of personal hygiene and of medical care in the Army.

The third group does not show a very different rate in Army and civil life. It includes some of the less common diseases of the Army age—diphtheria, syphilis, apoplexy, pleurisy, simple peritonitis, acute nephritis. It includes also appendicitis and suicide which are about three-fourths as common in Army as civil life.

To summarize: The greatest defect in the defense of the Army against death by disease lies in inadequate protection against communicable (especially contagious) diseases. The crowding of camp life brings special dangers which must be met by special precautions beyond those necessary in civil life. These precautions are particularly necessary when the troops come from rural States.

It is the function of the Surgeon General's Office to fight microorganisms in order that the General Staff may have live and effective men to fight for democracy.

While the record of diseases described in the foregoing pages may make disheartening reading, still the record must be made—the facts must be faced, and our limitations must be overcome by research that shall lead to knowledge. Yet in this record of disease there is ground for encouragement rather than pessimism. A comparison with other American wars shows how great has been the advance of preventive medicine and how much it has increased the Army's effectiveness. Instead of the hundreds of deaths from typhoid during the Spanish-American War, the Army in 1917 suffered only 18 deaths from this disease. The first six months of the mobilization of the Federal Army during the Civil War, July to December, 1861, are nearly comparable as to season with the period July to December, 1917. Let us compare the morbidity for certain common diseases in the two Armies, 56 years ago and last year.

Table No. 136 shows the relative admission rate of certain common diseases in the Army July to December, 1861, and July to December, 1917. Figures denote actual number of cases of disease reported in the entire Army, of white troops. As the strength of the Army in 1917 was about three times that of the Army of 1861, the actual number of cases in 1861 has been multiplied by three.

TABLE No. 136.—*Admissions, first six months Civil War and present war compared (white troops).*

Disease.	First half-year of Civil War ×3.	United States enlisted men, July-Dec., 1918 (first half-year of present war).
Measles	41,815	46,428
Pneumonia	9,246	7,675
Mouth and throat infections	125,445	52,462
Mumps	6,336	7,843
Typhoid fever	10,068	225
Minor intestinal inflammation	244,107	10,985
Malaria	167,163	1,796
Tuberculosis and hemorrhage of lungs	7,998	6,850
Syphilis	14,790	7,755
Gonococcus infection	18,849	45,027
Total	645,817	187,046

This table, represented graphically in Chart 69, speaks for itself. Aside from gonococcus infection (which is probably commoner now than formerly, and is almost certainly more carefully diagnosed) none of the diseases of the list show an important increase over 1861. Measles and mumps apparently show a slight increase. The great reductions in disease are those brought about by improved sanitation. Diarrhea and dysentery are reduced from 244,000 to 11,000, due to treatment of feces and fighting the fly. Typhoid fever is reduced from 10,000 to 225 by keeping down the fly and especially by protective inoculation; typhoid, the former great scourge of armies, has become as negligible as smallpox. Malaria has been reduced from 167,000 to less than 2,000, due to elimination of mosquito breeding areas.

Mouth and throat infections have been cut in third by better ventilation, preventing of crowding and spitting, and the isolation of carriers. The result for the various diseases amounts to a saving during this half year of mobilization of about half a million cases of sickness and the rescuing of the lives of ten thousand soldiers. Of deaths in 1917 there were 2,984 in Army enlisted men in the United States. For the same strength in the Civil War there were 13,959. Thus the advance in sanitation and preventive medicine since 1861 has saved in the first half year of the war over 10,000 lives.

F. FRACTURES.

The total number of fractures occurring in the Army for 1917 was 6,469, of which 89.6 per cent were simple, 7.4 per cent compound and 3.1 per cent comminuted.

I. Simple Fractures.

Two thousand and thirty were caused by falls, 2,006 by agents not stated, 498 by crushing accidents, 430 by automobiles, and 320 by animals. Other agents as motor cycles, railroad accidents, machinery, etc., caused a lesser number. Only 39 simple fractures were caused by aeroplane accidents.

The metacarpals, radius, rib, clavicle, tibia, and fibula were the most common locations and comprised 58.8 per cent of all cases.

The metacarpals were not divided into individual groups to determine the proportion of fractures of the various bones.

There were 674 fractures of the radius; 76.8 per cent were of the lower, 7.1 per cent the middle, and 3.7 per cent the upper third. This does not include 43, or 6.4 per cent, of cases in which the location of the fracture was not stated; 36, or 5.3, per cent through the head; and 4, or 6 per cent through the neck. The total number of days lost was 14,292.

There were 2 cases of fracture involving the first rib, 15 the second, 27 the third, 17 the fourth, and 37 the fifth, 40 cases with one rib fractured, 122 with two, 17 with three, and 8 with four. In 50 per cent the location or number of ribs fractured was not stated. In two cases the patient died, 1 with two and 1 with three ribs fractured. The days lost were 6,214.

Fracture of the clavicle occurred in 526 cases; 21, or 4 per cent, were of the inner; 194, or 36.9 per cent, the middle; and 138, or 26.2 per cent, the outer third. In 173, or 32.9 per cent, the location was not stated.

Fracture of the tibia occurred in 490 cases, of which 207 were accompanied by fracture of the fibula, 1 the astragalus, and 1 the radius. In cases without an associated fracture of the fibula, 137, or 48.7 per cent were of the lower; 73, or 26 per cent, the middle; and 32, or 11.4 per cent, of the upper third. This does not include 32, or 11.4 per cent, without associated fracture in which the location was not stated and 7, or 2.5 per cent, in which the fracture was through the head of the bone. Of the fibula fractures, 115 were of the lower, 57 of the middle, and 8 of the upper third. The location was not stated in 26 cases and in 1 the fracture occurred through the neck. The total days lost in fracture of the tibia alone were 10,799, and in cases where both tibia and fibula were fractured, 10,867 days.

The fracture of the fibula alone occurs in 466 cases; 371, or 79.6 per cent, being of the lower; 30, or 6.4 per cent, through the middle;

INJURIES AND ASSOCIATED FRACTURES

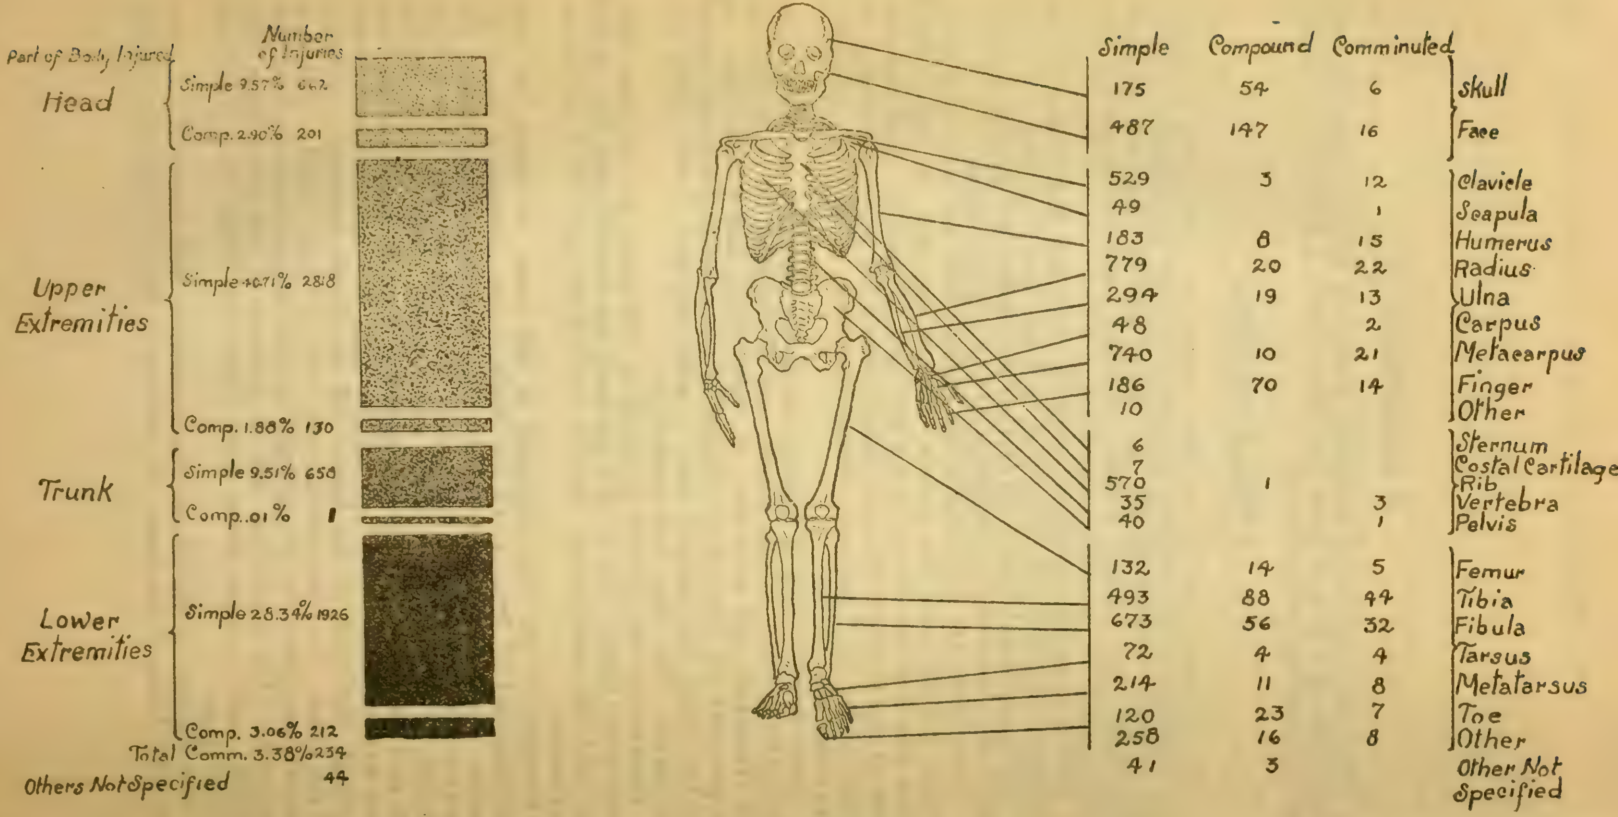

CHART No. 70.

and 27, or 5.8 per cent, through the upper third. In 38, or 8.2 per cent, of cases the location was not stated. The total number of days lost was 15,059.

Operation was performed on 316 patients: 12 being complicated by infection, 3 by malunion, and 1 by nerve injury. The method of operation was not stated in 103 cases; among these 1 patient died.

Plaster of Paris cast was applied to 78 patients after the reduction of fracture. Wiring was the method of operation in 37 cases, bon graft in 3, and the application of a band in 1. The removal of bone fragments was necessary in 10 fractures. Decompression was performed for 6 cases, with a mortality of 33.4 per cent.

II. Compound Fractures.

Of the causative factors producing this type of fracture, 140 were by agents not stated, 61 by falls, 59 by animals, 42 by crushing, and 40 by automobiles. Only 4 were caused by aeroplane accidents, and 1 by hand grenade. Other agents were the cause of a lesser number.

The tibia, nasal, superior maxilla, and skull were the most common locations and comprised 52.8 per cent of the cases.

There were 87 compound fractures of the tibia, 33 occurring without an associated fracture of the fibula. Of these, 7, or 21.2 per cent, were of the lower; 15, or 45.5 per cent, of the middle; and 6, or 18.2 per cent, of the upper third. Two cases, or 6 per cent, were through the head, and in 3, or 9.1 per cent, the location of the fracture was not stated. The fibula was fractured in 54 cases, 19 being of the lower, 26 of the middle, and 5 of the upper third. In 4 cases the location of the fracture was not stated. The total number of days lost in fracture of the tibia alone was 1,993, and in cases where both tibia and fibula were broken, 3,167.

There were 69 cases of fractures of the nasal bone with a total of 637 days lost, 9 cases of the superior maxilla with 186 days, and 29 cases of fracture of the skull with 174 days. Of the skull fractures, 21, or 72.4 per cent, were at the base; 7, or 24.1 per cent, at the vault; and in 1, or 3.4 per cent, the location was not stated.

Operation was performed on 80 patients, 8 being complicated by infection. The method of reduction was not stated in 23 cases, 10 required amputation of all or part of the upper extremity, 4 were reduced by the application of a plate, 4 by wiring the fragments, and 2 by bone graft. Amputation of all or part of the lower extremity was necessary in 9 cases; among these 2 patients died. Decompression was performed in 5, with a mortality of 40 per cent.

III. Comminuted Fractures.

Fifty-two were caused by falls, 48 by agents not stated, 30 by crushing, and 21 by automobiles. One was caused by aeroplane, 2 by pistol ball, 4 by rifle ball, 1 by shell, and other agents figure as causative factors in a varying proportion of cases.

The tibia, metacarpals, humerus, and radius were the most common locations and comprised 47.2 per cent of all cases.

There were 44 cases of fracture of the tibia, 18 without and 26 with an accompanying fracture of the fibula. In 4, or 22.2 per cent, of cases the bone was fractured in the lower; 9, or 50 per cent, in the middle; and 4, or 22.2 per cent, in the upper third. In 1 case the location was not stated. Of the fibula fractures, 10 were of the lower, 10 the middle, and 2 the upper third. In 4 cases the location was not stated. The total number of days lost in fracture of the tibia alone was 1,243 and in cases with both tibia and fibula fractured 1,649.

There were 21 cases in which the metacarpal bones were fractured, 1 case having two and 1 case five bones broken. The total number of days lost was 385.

The humerus was fractured in 15 cases, 7, or 46.6 per cent, being in the lower; 6, or 40 per cent, the middle; and 1, or 6.6 per cent, the upper third. The total number of days lost was 610. One case had an associated fracture of the ulna with the loss of 48 days.

The radial fractures were 14 in number; 7, or 50 per cent, were of the lower; 5, or 35.7 per cent, of the middle third; 1, or 7.1 per cent, through the head; and 1, or 7.1 per cent, in which the location was not stated. No associated fractures were present and the total days lost were 294.

IV. OPERATIONS.

Operation was performed on 27 patients, 3 having a complication of infection. Amputation, all or in part, was necessary in 1 case of the upper and in 3 of the lower extremity. The method of opertion was not stated in 5, and 3 required the removal of bone fragments.

There were 31,057 operations performed in the Army during 1917, 28,664 for disease and 2,393 for traumatism. Operations for the correction of physical defects of drafted men form a large percentage of the total number.

Chloroform was the anesthetic of choice for 493 operations, ether for 11,325, and gas for 380. Local anesthesia was used for 11,356 operations and in 7,503 the anesthetic was not stated.

Recoveries numbered 26,911 and the incomplete cases 3,882. The mortality was ninety-eight one-hundredths of 1 per cent.

The appendicectomies were 3,849 in number, 3,667 without and 182 with drainage. Recovery took place in 3,030 cases, 71 patients died, and 748 cases were incomplete. Among the cases requiring drainage, 49 had a complication of abscess, resulting in the death of 2 patients, 58 acute diffuse peritonitis with the death of 27, and 23 with acute local peritonitis with the death of 10. In 44 cases the appendix was gangrenous, resulting in the death of 5 patients, or a mortality of 11.4 per cent.

The herniotomies were 2,620 in number, of which 16 were femoral, 2,592 inguinal, 9 lumbar, and 3 umbilical. Of the cases requiring inguinal repair, 17 had complications, 6 were strangulated hernias, and 1 relaxed inguinal rings.

Mastoidotomy with drainage was performed in 238 cases of mastoiditis, with a mortality of 4.6 per cent. Mastoiditis complicating measles required operation in 42 cases and in 1 of mumps.

There were 336 cases of rib resection with drainage, with a mortality of 15.2 per cent. Measles, lobar and broncho-pneumonia were the leading primary diseases requiring this operation when complicated by suppurative pleurisy.

Thoracotomy with drainage was performed in 93 cases, with a mortality of 25.8 per cent. Lobar and broncho pneumonia were likewise the leading primary diseases requiring this operation.

The amputations were 517 in number. Recovery occurred in 449 cases, 8 patients died, and 60 remained as incomplete. Traumatic amputation required amputation of all or part of the upper extremity in 48 cases, compound fracture in 10, and gunshot wound in 43. Crushing injury required amputation of all or part of the lower extremity in 43 cases, gunshot wound in 26, compound fracture in 9, and traumatic amputation in 8.

Tonsillectomy was performed in 3,835 cases of hypertrophied tonsils, with a mortality of one-tenth of 1 per cent. Adenoidectomy was an additional operation in 367 cases in which adenoids were associated with hypertrophied tonsils.

There were 2,155 operations for hemorrhoids. Phlebectomy was the method of operation in 690 cases, ligation in 440, and clamp and cautery in 1,009.

Nephrectomy was performed for 3 cases of hydronephrosis, 2 of pyonephritis, 1 of pyonephrosis, and 3 of nephrolithiasis, and 1 of nephritis.

Gastroenterostomy was performed for 20 cases of gastric ulcer, 13 of duodenal ulcer, and 1 of intestinal obstruction. Recovery took took place in 22 cases, 1 patient died, and 10 remained as incomplete.

The comminuted fractures requiring operation were 27 in number. Of these, 3 were reduced by the application of a plate, 3 by wiring the fragments, and 1 by bone graft. Laminectomy was performed on 1 patient and plaster of Paris cast was applied to 4. The method of operation was not stated in 6 cases.

The compound fractures requiring operation were 80 in number. Of these, 4 were reduced by the application of a plate, 4 by wiring the fragments, and 2 by bone graft.

There were 316 simple fractures requiring operation, 38 being reduced by the application of a plate, 1 by band, 6 by bone graft, and 37 by wiring the fragments. Laminectomy was performed on 2 patients.

Trephining was performed in 8 cases of head injury, with a mortality of 37.5 per cent.

The thyroidectomies were 23 in number. Of these, 15 were for simple and 8 for exophthalmic goiter.

Enterorrhaphy was performed in 4 cases for the result of traumatism. The mortality was 75 per cent.

Enucleation of the eye was performed in 30 cases for the result of traumatism; 6 were for gunshot wounds.

TABLE No. 137.—*Battle wounds, 1917.*

Number.	Traumatism.	Number.	Causative agent.	Number.	Location of tissue.	Number.	Operation.	Remaining.	Duty.	Died.	Days lost.

G. ACTIVITIES OF THE MEDICAL DEPARTMENT.

1. Chief Surgeon's Office, A. E. F.

1. GENERAL REMARKS.

It is interesting to note that, even before the staff of the commanding general arrived in France there were already there six fully equipped base hospitals. These hospitals were then at work. At the annual meeting of the American Red Cross in December, 1915, two great divisions were made in this work. First, the Department of Military Relief and, second, the Department of Civilian Relief. Col. Jefferson R. Kean, Medical Corps, United States Army, was selected as the first Director General of Military Relief. He conceived the idea of organizing complete base hospital units. His subsequent plans were approved by the Surgeon General and the formation of American Red Cross Base Hospital units was begun. Before the United States entered the war, not less than 39 of these base hospitals were organized. The full number authorized by the War Department was 50. These were completed during the summer of 1917. Each of them consisted of officers, nurses, and men, all pledged to enter the military service if called in event of war.

In addition there were also organized hospital units, ambulance companies, and surgical sections, emergency nursing detachments, and sanitary trains. The hospital units were organized to give an outlet to the desire for service on the part of many medical schools which were not of sufficient size to provide the necessary personnel for a complete base hospital. These hospital units were about one-half the size of the base hospitals and were planned for 250 beds. They have since proved of great value in manning camp hospitals in the American Expeditionary Force where the larger unit was not required. All the 17 ambulance companies organized prior to the entry of our country into the war have been incorporated into the Army Ambulance Service. Surgical sections were also organized, a considerable number of which have been called for active service.

At the request of the British and French mission, the War Department called upon the American Red Cross to furnish six base hospitals for immediate shipment to France to serve with the British Expeditionary Force. Between May 8 and 25, 1917, the six organizations sailed. These organizations were as follows:

Base Hospital No. 4, Cleveland, Ohio.
Base Hospital No. 5, Boston, Mass., Harvard unit.
Base Hospital No. 2, Presbyterian Hospital, New York City.
Base Hospital No. 10, University of Pennsylvania.
Base Hospital No. 21, St. Louis, Mo.
Base Hospital No. 12, Northwestern University, Chicago.

A Regular Army medical officer was placed in command with a Regular Army medical officer as adjutant. There was also a small nucleus of from 4 to 15 enlisted men of the Regular Medical Service.

It should be noted that on September 4, 1917, a hostile aeroplane attacked the hospital group, Base Hospitals Nos. 12 and 15, which were grouped with several British general hospitals. As a result, one first lieutenant, Medical Officers' Reserve Corps, two privates, first class, of the Medical Department, and one private, first class, Medical Emergency Reserve Corps, were killed. Three lieutenants, six privates, first class, or privates, were wounded. Thus the first members of the American Expeditionary Force to lay down their lives or suffer wounds in the great war at the hands of the enemy were not from among the combatant forces, but from those who were engaged in deeds of mercy.

The first chief surgeon of the American Expeditionary Force was Col. (now Brig. Gen.) A. E. Bradley, Medical Corps. When he later returned to the United States on account of his health, Col. (now Surgeon General) M. W. Ireland was appointed in his place.

The chief surgeon's office was organized in six divisions—1, hospitalization; 2, sanitation and statistics; 3, personnel; 4, supplies; 5, records and correspondence; 6, gas service. The chief surgeon's office was later consolidated with the Medical Department of the Service of Supplies. It was then divided into the following divisions:

1. Division of Hospitalization. Evacuation and Hospital Administration.
2. Division of Sanitation. Sanitary Inspection, and Medical Statistics.
3. Division of Personnel.
4. Division of Medical Supplies.
5. Division of Finance and Accounting.

2. HOSPITALIZATION.

A large number of hospital beds are now available, and plans are already made to provide a sufficiant number, or at least as large a number as practicable. A number of buildings are being constructed and a number are also being obtained from the French Medical Service. Hospital trains have also been provided. Two of these were purchased in France and a number from the English Government.

3. EPIDEMIOLOGY.

The hardest problem that the medical officers of the American Expeditionary Force and the Navy have to grapple with in safeguarding the health of the men is the control of epidemic diseases. Contagious diseases are found in practically all organizations arriving at base ports. This is well nigh unavoidable, due to the necessary overcrowding on shipboard, and the inactivity and lowered vitality of the men. Practically every threatened epidemic of communicable disease has been traced back to the base ports.

Weather conditions and overcrowding in billets and barracks increase the spread of these diseases. There are certain factors, however, which have been repeatedly stressed by the office of epidemiology which are capable of materially helping the situation. Among these the following should be noted: (1) The absolute necessity of personal cleanliness, (2) the danger of overcrowding, not only in the matter of bed space, but crowding about the stoves in the barracks.

As a commentary on the sometimes doubted efficiency of the Army inoculation and vaccination, it is worthy to note that after the death of an officer from smallpox and the occurence of several cases of typhoid it was found that in the smallpox case and in nearly every case of typhoid the individuals had for some unknown reason failed to be vaccinated or inoculated, or that such artificial immunization had been reported unsuccessful.

4. LABORATORY SYSTEM.

This important division has been thoroughly organized with a central laboratory in a suitable place housed in suitable buildings, which were secured from the French Medical Service. One of the main functions of this central laboratory is as follows:

> The standardization of technical methods, the supply of standard materials, diagnostic and therapeutic sera, vaccines, cultural media, special mobile outfits, and personnel for the investigation and control of transmissible diseases and the training of personnel for special laboratory problems arising during the course of the war.

This laboratory has since proved of the utmost importance in safeguarding the health of the Army. Several large base laboratories have also been established.

5. SANITARY INSPECTION.

Sanitary inspections are made periodically. There are two general sanitary inspectors on duty in the office of the Chief Surgeon. These officers make inspections of base hospitals, depots, camps, and other places as necessary. There are two especially great problems affecting the health of the Army. These are prevention of (1) skin diseases and (2) venereal diseases.

6. PREVENTION OF SKIN DISEASES AND BODY LICE.

One of the greatest problems which has arisen in maintaining the health in all armies at all times has been that of body vermin. This problem has been made especially acute in the present event because of the trench life bringing with it congested quarters in dugouts and necessarily unsanitary conditions. The experience of the British in handling this problem is brought together briefly in the following summary:

> The main factors in keeping troops free from vermin are personal cleanliness, accomplished by bathing and frequent washing of the clothes. But little help in this is given by the use of chemical agents, and their use is rather discouraged by the British authorities as producing a false sense of security.

This problem can probably best be handled by thorough and frequent bathing, frequent laundering of the clothes, with additional steam or hot-air disinfection as necessary. The disinfection and sterilizing can best be handled by the Medical Department and the laundry by the quartermasters.

7. VENEREAL DISEASES.

The American attack on venereal diseases has been upon the following lines:

> 1. The education of soldiers and civilians as to the physical dangers of venereal diseases.

2. Discouragement tending to prohibition of the use of all forms of intoxicants, the idea being that the sexual impulses are always excited by such stimulation and self-control diminished.
3. Repression of all forms of illicit sexual intercourse, both clandestine and public, under the theory first advanced by American medical men that the exercise of the sexual functions is not essential to health and manly vigor.
4. A thoroughgoing provision for, and use of, the prophylactic treatment.
5. The employment of stern measures and adequate punishment for those contracting venereal disease.
6. The calling into play of physical, social, moral, even religious factors, that might aid in keeping men free from illicit sexual intercourse and thus free from disabling venereal disease. The encouragement of the Y. M. C. A. and allied agencies in their propaganda, making for physical, material, social, and moral betterment, forms a notable example of this.

The chief surgeon is convinced that the campaign against venereal diseases which has been carried on is progressing satisfactorily and that the rate is beginning to show the satisfactory result of the campaign.

8. AMBULANCE UNITS.

For some time prior to the entrance of the United States into the war, ambulance companies had been organized in France of volunteers chiefly from colleges in the States. This movement received considerable extension in the early part of 1917 as it became evident that the United States would enter the war. It was suggested by the French mission that the United States should organize these volunteers on a military basis. The organization of the United States Ambulance Service was authorized to consist of 160 sections. Of these 120 were to be organized in the United States and 40 in France.

When the organization was undertaken there were 45 volunteer sections in operation. When arrangements had been made for the enlistment in the voluntary sections, it was found that a large number of these men did not desire to enlist, either preferring to go into a combatant branch of the service or to go home. It was therefore possible to organize only 25 sections from the American Ambulance Service. From the personnel of the 15 Red Cross sections there were only enough enlistments to make 3 sections. These sections were reinforced by a number of sections which had been organized in Allentown, Pa.

The entire United States Ambulance Service with the French Army now consists of 77 sections, 49 of which were trained and organized in Allentown, Pa., and 28 of which are the original volunteer American sections as stated above. These sections are now doing duty with the French Armies at the front, with the exception of 3 serving in the entrenched camp in Paris, one headquarters section, and half a dozen in reserve at the base camp of the service.

The service is a part of the American Expeditionary Force, and in its organization, discipline, and supply is subject to the commander in chief, American Expeditionary Force. Its men are fed, clothed, and equipped and its motor vehicles, gasoline, oil, and spare parts are furnished by the American Government. When, however, its organized units pass into the zone of the front and report for duty to the French Direction des Services Automobiles, the disposition of these units passes absolutely under the French military authority and is in every way subject, as far as movements, station, and performance of duty are concerned, to that authority. The chief of the service can not issue orders affecting the movements of units in the zone of the front, and all orders affecting individuals and material pass through the French military authorities. Outside of the zone of the front, however, the chief of the service has exercised entire control over the personnel and material and over the units of the service, as well as the individual members, and over the base camp.

9. SUPPLIES.

When it became evident that war would be declared, the Medical Department authorities immediately set about organizing the country for production. Through its medical representative on the Council of National Defense an invitation was sent to all the great manufacturers in the country who produced articles used by the Medical Department to appear in Washington for consultation. Representatives of the Surgeons General of the Army and Navy and also representatives of the Public Health and Marine Hospital Service were present at this conference and outlines of procedure were adopted. Committees on the supplying of textiles, medicines, surgical instruments, dental supplies, etc., were organized. These proceeded to communicate with all the manufacturers with the object of meeting the needs of the Government, as shown by lists prepared in the Surgeon General's Office, based on an army of 1,000,000 men.

The country had been practically denuded of many of the needed articles by purchases rendered necessary by the mobilization on the Rio Grande. A large proportion of the instruments, drugs, medical and laboratory supplies, etc., had been manufactured in Germany or elsewhere abroad, and this supply was, of course, entirely shut off. The Japanese had begun to manufacture in a modest way, but it was evident that the great bulk of medical supplies must be secured from our manufacturers. The committee on instruments allotted to various firms the articles they were best equipped to supply, and in like manner provision was made for the making of dies for instruments. The great textile mills took over and divided among themselves, in proportion to capacity, the making of gauze and articles of kindred manufacture, and the glass factories did likewise for laboratory supplies. The greatest shortage appeared to be in the procurement of sufficient dental equipment, but the large manufacturers took up this matter also and, in addition, each dental surgeon from civil life was authorized to bring with him into the military service certain articles of absolutely necessary equipment, which were afterwards inspected and appraised by a board of officers and taken over by the Government after a just valuation.

10. MEDICAL SUPPLIES IN THE AMERICAN EXPEDITIONARY FORCE.

The medical supply problem in the American Expeditionary Force was especially complicated by the shortage of available bottoms. This was partially compensated for by purchase in France, England, and other allied and neutral countries. However, the facilities of France and England being strained to the utmost has resulted both in delays in completing contracts and inability to obtain certain items.

By the middle of August about 7,000 cubic tons of supplies had been secured at * * * and 8,000 more were due on requisition. There were, however, no veterinary supplies on hand, and the only dental supplies were the personal chests carried by the dental officers. An attempt was made to secure some from the French, a dentist and a veterinarian going to Paris for consultation with the purchasing officer.

On September 4 * * * was still the only port used in unloading medical supplies. In the seven weeks succeeding the arrival of the first shipment 9,000 tons had been unloaded and forwarded. The storing facilities were wholly inadequate; consequently all goods had to be rushed from the ships to freight cars. Though credit is given to the officers at * * * in moving the supplies through to the intermediate zone, there was great confusion, and storage facilities near the port were strongly urged.

As our forces began materially to increase, more and more requisitions were necessarily incompletely filled, as the shipments from the United States did not keep pace with the demand. This condition improved a little later, and by the middle of November the chief lack was in field medical supplies.

A number of supplies has been purchased in France and England through the respective Governments. It is interesting to note that the Medical Department placed the largest individual drug order ever given in England. It consisted of more than 22,000,000 tablets and more than 13½ tons of other drugs. These arrangements for purchase in France and England helped greatly in the solution of the supply problem.

It has been difficult at times to secure adequate storage facilities for the supplies.

11. ACCOUNTING DIVISION, MEDICAL SUPPLY DEPARTMENT.

This division has had a rather interesting and unique history. It was organized and brought to France as a separate detachment.

On September 26, 1917, an act of Congress was passed authorizing the Comptroller of the Treasury and the Auditor for the War Department to perform the duties of their offices and audit the accounts of the Military Establishment at any place other than the seat of government.

A colonel of the Regular Army was informed by communication from Washington in the early part of October that he would be selected for the purpose of collecting and taking to France a force of men qualified to audit the accounts of the Medical Department in France, and was ordered to proceed to Washington for consultation. Upon arriving there he was informed of the nature of the work and directed to obtain a sufficient force to correspond to an army of 2,000,000 men. The organization of the office of the Surgeon General in Washington was taken as a model and the auditor and various other department organizations who were engaged in similar work were consulted. In order to get men qualified for the character of the work they would probably be called upon to do, all the large banks in New York, Baltimore, Washington, Philadelphia, and as far west as Chicago, and a large number of the great insurance companies, railroads, and department stores were communicated with and requested to supply the names of men with the necessary qualifications who had already been drafted and were at the cantonments. This was followed up by a ready response and a great many names were obtained only to find out later that almost all of these men had already been assigned to duties that prevented their being available. The banks were then requested to furnish lists of the men who were about to be called, and by induction and regular enlistments the desired number was obtained. From first to last, 7 officers (including the commander) and 135 men were brought to France. Many of the latter, however, were intended as clerical help in the office of the chief surgeon, supply depots, division surgeons, etc.

In November a temporary office was established at the New York Medical Supply Depot, where the work of organizing was done. Recruits were examined as to qualifications and sent to Fort Jay, Governor's Island, for physical examination and were there stationed until the date of sailing. While at Fort Jay the detachment was thoroughly drilled, and classes were held in such subjects as would likely be involved in their work in France. Here, also, supplies were collected and plans made for the procedure and work of the detachment abroad.

The first section of the detachment, consisting of the commander, 4 lieutenants, and 100 men, left the United States on January 4, 1918, arriving at * * * January 17. They remained at the rest camp at this place until January 24, when they entrained for * * *. In this town, while awaiting orders to their permanent destination, the organization of the detachment was worked out and the members assigned to definite duties when the work of the unit should begin; plans of procedure were charted, and suggestions worked out for the improvement of the methods of handling money and property accounts of the Medical Department. While at * * * 25 members of the detachment were sent to the Intermediate Medical Supply Depot No. 3 at * * *, and 5 to the Advance Medical Supply Depot No. 1 at * * *. On February 13, the remainder of the detachment was sent to * * *, their permanent stations. The preliminary work of establishing an office was immediately begun, and about the 15th of March actual work was started in the room provided in Barracks No. 66.

The second section, consisting of 2 lieutenants and 35 men, arrived in France on the 9th of February, was promptly broken up, and only 2 members and the 2 officers were later assembled with the original unit.

With numerous transfers to medical supply depots and other Medical Department organizations the enlisted force was reduced to 37 members. One of the officers was sent to Paris for duty with the bureau of accounts, and one to the office of the purchasing board. On April 1 the unit was attached to the office of the chief surgeon, and has since operated as the finance and accounting division of that office. Then on May 1 the personnel of the chief surgeon's office and that of the finance and accounting division were consolidated.

Regarding the report of money and property operations of the Medical Department above mentioned, it is interesting to note that testimony has been received from the bureau of accounts, the Assistant Auditor for the War Department, and the Comptroller of the

Treasury that the Medical Department is the first department to submit such a report. The chief of the bureau of accounts desired to show the report to the chiefs of the various departments as a sample of what was possible along this line. It should also be noted that the Medical Department is the first of the departments to attempt to coordinate the financial and property operations in the United States and those of the American Expeditionary Force.

The question is often raised as to the value of accounting work to the actual prosecution of the war. Regarding this question two very important points have been clearly brought out in the work of this division. (1) The work is of great importance to those actually engaged in the prosecution of the war as making it possible for them to render an account to the people of the United States for the vast sums of money they have expended, as well as to assist in the economical expenditure of the same; (2) but, of far more importance than this, the accounting division is actually aiding in the efficient prosecution of the war as far as it concerns the Medical Department by helping to put the business dealings of the department with the French and English on a sound and equitable foundation. Many instances might be cited to show how intricate problems of business relations between the French and Americans have been tactfully adjusted, so that while amicable relations might continue, it would become clear that efficient service was demanded.

II. Division of Sanitation.

1. INTRODUCTION.

The mobilization of the National Guard, the concentration of the Regular Army into large camps, the hurried recruiting of the regular forces, the mobilization of the National Army, the great force of drafted men suddenly called from home life to a new environment, all these conditions have required the application of the total professional knowledge of the country to the vast and relatively new sanitary problems involved. The sudden call for shelter, food, clothing, conservancy, medical attendance, and the other things necessary to the health of the soldier could not be met at once in a manner wholly perfect.

It is a matter of history that all campaigns have been accompanied by epidemics of those diseases more or less peculiar to great aggregations of men. In the light of modern accomplishments in preventive medicine we expect that these Army diseases will be kept at the minimum, though not absolutely prevented. The mobilization, concentration, and movement of troops during the past year have been no exception to the general rule. Some epidemics have occurred, and the morbidity and mortality rates in the camps and cantonments have been higher than the minimum desired. These minimum rates have by no means been reached, but the present handling of a constant stream of men in the camps and cantonments will result in the formulation of improved laws of military hygiene, the application of which, it is expected, will allow large numbers of men to be brought into camp and to live there, with the minimum dissemination of the camp diseases.

The old Army scourge, typhoid, together with the paratyphoid group, has been practically eliminated by prophylactic inoculation with triple vaccine. The other intestinal infections have been controlled by general sanitary methods. The class of diseases now of importance throughout the Army is that group in which the method of spread is by means of secretions from the respiratory tract, viz, meningitis, pneumonia, measles, diphtheria, scarlet fever, and mumps. With the experience of the past year as a guide and with the aid of the best medical talent of the country, it may be confidently expected that the study of these diseases will yield new facts regarding the modes of infection and the methods of prevention which will prove of immense benefit not only to the soldiers during the present war, but also to the entire population of the country thereafter.

2. THE WORK OF THE DIVISION OF SANITATION.

Organization.—A division of field sanitation was informally established on May 24, 1917, by the assignment of an experienced sanitarian from the Medical Corps of the Army. Additional personnel has been added from time to time and the functions of the division have gradually expanded to embrace the whole subject of general military sanitation. For administrative purposes, the division is subdivided into sections which are indicated below:

(*a*) *Section of inspection.*—A group of specially trained medical officers of long service is constantly engaged in making routine and special inspections of all large camps, cantonments, hospitals, and other stations. Their duties originally pertained chiefly to sanitary and administrative matters within camps and cantonments. As the service of hospitals developed, their duties were extended to include hospital inspections also. One of these inspectors is stationed at San Antonio, Tex., and visits the large stations in the Southern Department. The other officers are stationed in Washington and return to that city after their inspection tours, spending about half their time in office duty. This system enables the Surgeon General to keep in close personal touch with the sanitary situation at all stations. The officers making inspections, upon their return to Washington, confer personally with the departments and divisions concerned in the correction of sanitary deficiencies and take a personal interest in following up such matters and obtaining such remedial action as is practicable. It has been found that in most instances this procedure secures far more rapid and satisfactory results than can be obtained by the usual written report emanating from the command where the defect exists. At the conclusion of an inspection the sanitary inspector makes a report to the commanding officer regarding the defects he has found, and submits recommendations for such remedial action as lies within the power of local authorities.

The scope of the sanitary inspection differs materially from that made by the Inspector General's department. Less stress is laid on details of a purely military nature and much more stress is laid on matters largely technical, such as general camp sanitation, nursing and professional care of the sick, competency of medical officers, handling of infectious diseases, prevention of venereal disease, management of quarantine and detention camps, extra cantonment health activities, medical supplies, hospital construction, laboratories, special diets, training of sanitary trains, mosquito eradication, water purification, sewage disposal, etc. A medical officer who has expert knowledge of the louse problem makes inspections with a view to determining the prevalence of lice and the steps necessary for their eradication. Inspections relating especially to technical sanitary engineering problems are made by officers belonging to the sanitary engineering section of this division.

(*b*) *Section of communicable diseases.*—This section is composed of officers who are specially trained in the study and control of communicable diseases. The work of the section includes the preparation of graphic charts and reports for the use of the Surgeon General and for general dissemination. The activities of this section are indicated by the report on communicable diseases appearing under Paragraph 14.

(*c*) *Section of sanitary engineering.*—This section, consisting of officers of the Sanitary Corps with training as sanitary engineers, advises on questions of water supply, sewage disposal, drainage, and mosquito control in all camps, cantonments, and other stations. Every large camp has one or more officers of the Sanitary Corps on duty as assistant to the camp surgeon. These officers supervise drainage and mosquito work, and in some camps have charge of the operation of water purification and sewage-disposal plants and the handling of garbage.

At several of the southern camps where there was a probability that malaria might occur, enlisted men of the Sanitary Corps have been assigned in detachments varying from 50 to 200 men for the purpose of furnishing the actual labor required in connection with drainage and oiling operations. This has been necessary in view of shortage of civilian labor in many localities. These enlisted men are colored. White men of the Medical Department have also been assigned as overseers of enlisted laborers from labor battalions. This force is under the immediate control of an officer of the Sanitary Corps.

(*d*) *Section of current vital statistics.*—This section receives and compiles current statistics relating to morbidity and mortality rates, based on daily and weekly telegraphic reports from camps and stations in the United States and the weekly cable from forces overseas. Publication and general distribution of the "Weekly Bulletin on Disease Conditions among Troops in the United States" has been carried out and the mailing list numbers about 300. The statistics compiled by this section are used as the basis of a weekly summary of health conditions which is prepared by the chief of the division and given to the press for publication. These statistics are also used by the section of communicable diseases for the preparation of graphic charts and tables. Although not mathematically correct, mistakes and corrections being inevitable, these figures are sufficiently accurate for all practical current purposes in the current medical administration of the Army stations. The weekly report to the Secretary of War and the Chief of Staff and the system of compilation have been the subject of much favorable comment, and the report made use of by other bureaus of the War Department in compiling current statistics.

(*e*) *Section of personnel.*—This section is engaged in the mobilization of trained medical personnel for the camps, for mobile divisions, and for other stations and organizations; the changes in their distribution; and the recording and listing the medical staffs of the camps. The chief medical officers, division surgeons, camp surgeons, sanitary inspectors of divisions and camps, depot brigade surgeons, epidemiologists, and assistants of special importance are selected by the division of sanitation and are held to account for the proper performance of their duties. There has already developed an acute shortage of trained medical officers for the important administrative duties, but by a process of gradual training of subordinates for higher positions it is fully expected that satisfactory personnel will ultimately be fitted into all of these positions.

The following subjects with which the division of sanitation has been concerned have been of especial importance and are separately discussed:

3. CAMPS AND CANTONMENTS; ACCOMMODATIONS FOR ENLISTED MEN, AIR SPACE AND VENTILATION; OVERCROWDING AND ITS EFFECT UPON THE TRANSMISSION OF DISEASE.

The original plans for the concentration of the Army were for 32 large stations. Sixteen were for National Guard divisions. These were camps with floored and framed tents and wooden mess halls, kitchens, and regimental infirmaries. Sixteen were for National Army divisions, to be composed of drafted men housed in frame cantonments.

The cantonments to be built for the new divisions were needed at once and plans were drawn by the construction division of the Quartermaster General's Office. The barrack plans were objected to by the Surgeon General, and a "board to examine the housing plans" was appointed by the Secretary of War. This was composed of the Surgeon General and three eminent officers of the Medical Reserve Corps.

The board found two grave sanitary defects in the plans: "First, overcrowding, i. e., the men in the dormitories are too close together; and, second, there are too many men in each dormitory. The amount of cubic space allowed to each man averages about 338 cubic feet. This is altogether too small." The board recommended that the cubic air space per man be increased to 500 cubic feet; that the unit to be housed in each barrack be reduced to 30; that changes be made in the plans to secure increased space and ventilation; and that additional barracks be built to lessen the crowding.

When the drafted men were accommodated in the barracks of these cantonments it was found that, as a result of military necessity, overcrowding was the rule and that new cases of pneumonia and meningitis were becoming so frequent as to occasion alarm. It was therefore recommended that the cubic space and the square floor space per man be immediately increased so as to provide a minimum of 500 cubic feet and 45 square feet, respectively, in each squad room; that in all barracks the men be required to sleep with the feet of one man opposite the heads of the two adjacent men, this to allow of at least 5 feet separation between the heads and so decrease the chances of spreading respiratory diseases by droplet infection; that the placing of bunks in groups of twos or fours should be prohibited; and that where double-deck bunks were used, the cubic air space and square floor space should be 1,000 and 90 feet, respectively.

Later, because of the rapidly increasing military force and the tendency to overcrowd men in barracks, it was recommended that the authorized man capacity of barrack dormitories be stenciled on the doors, the standard to be 50 square feet of floor space and at least 500 cubic feet of air space per man. The newer barracks are planned to house not over 34 men in a room, and the individual rooms are not connected with each other.

In the National Guard tent camps it was originally the intention of the War Department to house 12 men in one tent. This was because of a shortage in tents; and it was planned to reduce the number to 9 when the tentage supply was increased. Overcrowding in the tent camps became increasingly important and after a personal inspection of certain camps, the Surgeon General recommended that no more than 5 men be accomodated in one tent, which would allow a little over 50 square feet of floor space for each man. Because of the shortage of tents it was not possible at all times to secure this increase in floor space.

It may be stated that these recommendations were acted upon in as far as the War Department felt able to carry them out and that the improvements brought about in floor space and air space are now the rule rather than the exception. The danger from overcrowding is undoubtedly in the increased opportunity for droplet infection from man to man.

4. CLOTHING OF ENLISTED MEN.

The mobilization of the National Guard and the concentration o drafted men into the cantonments began in August, 1917. Reports at once began to be received in this office of shortage of clothing in both camps and cantonments. Regular Army units also reported this condition. There was a particular shortage of overcoats. Outer garments were generally of khaki; and woolen underwear, which was intended to make up for the shortage in woolen outer clothing, was frequently not sufficient in amount. There was also an insufficient supply of blankets.

This serious deficiency, which resulted from the military necessity of calling a large number of men to the colors before sufficient clothing could be provided, existed well into the winter and it was not unti February, 1918, that the reports from the commands indicated tha the enlisted men were adequately clothed. The exposure to which the men were subjected in the cold weather of the winter of 1917 undoubtedly was one of several predisposing factors in the causation of sickness in camps.

5. WATER SUPPLY, SEWAGE DISPOSAL, GARBAGE DISPOSAL, ETC.

With the increased population of Army concentration points particularly in the National Army cantonments and the Nationa Guard camps, the questions of adequate water supply, sewage treat ment, garbage disposal, etc., has been of increasing importance The large tent camps were originally without sewers, and the pi latrines, although generally maintained in good sanitary condition used up large areas of ground. For this reason the consideration of another method of sewage disposal became necessary. Sewers are now being built in these camps which will take care of this problem, but with an additional demand upon the water supplies which in some camps have never been satisfactory in amount. The sewage disposal plants of the cantonments were built to accommodate a certain strength of command which has generally, of necessity, been greatly exceeded with a resulting improper treatment of sewage. Numerous complaints have arisen, inspired by the nuisances resulting within or outside the reservations. Extensive alterations have been recommended.

These subjects have been investigated and recommendations have been made in regard to them by a staff of expert sanitary engineers on duty in this division. Certain aspects of the treatment of sewage and water supply have necessitated original study of the problems, new data being required on which to base specific recommendations.

6. MOSQUITO PREVENTION AND CONTROL.

The situation of Army cantonments and camps in malarial regions and the importation into them of malarial carriers have placed particular emphasis upon this problem. Extensive drainage projects have been surveyed and carried out by sanitary engineers of this division, and very considerable amount of maintenance and other anti-mosquito measures is now going on under the immediate care of the Medical Department. Recommendations were made early in the year for the screening necessary to prevent the entrance of mosquitoes into buildings occupied by the men. These recommendations include screen vestibules, requiring passage through two screen doors, at all Southern camps. The importance of detecting and treating malaria carriers has been emphasized.

7. FLY PREVENTION AND CONTROL.

The importance of this subject has not been minimized. Recommendations have been made for fly trapping, fly "swatting," poisoning and the use of fly papers, along with the methods for the prevention of breeding which are generally known to the Army and have constantly been enforced. Traps, paper, and "swatters" are now regularly furnished by the Quartermaster Corps. Screening of kitchens, barracks, and latrine shelters has been pushed.

8. MOVEMENT OF TROOPS; INSPECTIONS MADE TO PREVENT TRANSFER OF SICK.

Military considerations have been the governing factors in the movements of troops from camp to camp. Transfers from National Army camps were made to fill up National Guard divisions, and transfers of detachments composed of special details were common during the early history of the camps. Some of these movements were made over long distances, so that men were kept for two or more days in the coaches of troop trains. Epidemics have been traced in some instances to these movements. In order to prevent, as far as practicable, the transference of men sick with communicable diseases, recommendations were made that no troops be permitted to leave one station for another, or for overseas, without critical inspection for the detection of possible disease, and also that contacts of meningitis, measles, and scarlet fever cases, and also those infected with venereal disease, be retained at the station. Instructions were issued by the War Department directing compliance with these recommendations, and also requiring that similar inspections be made at ports of embarkation before commands were allowed to board ship. This led to a marked congestion of "contact cases" at ports of embarkation. Certain cases of infectious disease, unrecognized during the inspection made at the station of departure, appeared en route to the ports, or were later detected and excluded from the embarking command. With the rapid movement of troops to the embarkation ports, a considerable piling up of sick, of contacts and of "carriers" at these points became inevitable. Suitable hospital accommodations were at hand or were secured, however, and the troops which were marched aboard the transports were as effectually screened of their sick and contacts as was possible.

9. LOUSE INFESTATION.

The contact of individuals aboard transports is very intimate and conditions are such that the transference of parasitic insects from man to man is unusually easy. This is especially true as regards the louse. Reports from abroad indicated that commands debarked "over there" were frequently carrying a high percentage of louse-infected men. This question has been carefully studied by the expert entomologists of this division. Based upon their reports, delousing stations have been recommended at certain embarkation ports, at all large camps and at recruit depots. It has been found that the percentage of louse infestation among the colored stevedores and the labor battalions is considerable, and that the white soldiers are relatively free from lice. The possible importation, by returning troops, of lice which are infected with typhus and trench fevers is regarded as a problem worthy of the closest attention, and the delousing plants recommended will serve the double purpose of cleansing the outgoing and the incoming troops.

10. UNCINARIASIS.

The presence of hookworms in the men coming from the Southern States was considered an important predisposing factor in the causation of the infectious diseases which have been disproportionately frequent among these men. This is in accord with the findings of Army medical officers who have studied this question in previous years. This division has taken steps to secure the extermination of the worms in infested men from Southern States. Extensive surveys made by the laboratories in the camps have been followed by immediate treatment of the infected.

11. THE PHYSICAL EXAMINATION OF DRAFTED MEN.

The national defense act, in its application to the physical examination of the drafted men, has resulted in many readjustments of the routine methods of recruiting formerly in use in the Army. The examinations of registrants by local boards at their homes, and again by Army medical officers at camps, have not been as homologous as could have been desired. The original standards prescribed by the Provost Marshal General for the local boards were not the standards which were required by the Regular Army. Rejections in camp were often regarded as criticisms of the professional abilities of the physicians of local boards, while Army medical officers were apt to regard the selectives sent to them as poor material out of which to select soldiers.

The standards for volunteer enlistments in the Regular Army were used at recruit depots for the examination of registrants inducted at the depots and rejections were often made of men who were passed by local boards under the selective-service regulations. Modifications and adjustments of the regulations became necessary as it developed that men who were accepted for service and had undergone training finally to be dropped as unfit for overseas service, their places being filled by untrained men from the later drafts. This was an expensive process for the Government and interfered seriously with the training of troops.

A board of medical officers was appointed to revise the physical standards, and as a result there is now a fixed standard for the physical examination of all men entering the Regular Army, the National Guard, and the National Army. All medical examiners have been issued similar regulations, the local boards having been supplied by the Provost Marshal General and officers of the Army by The Adjutant General. Already a marked improvement has resulted.

12. EXTRA CANTONMENT AREAS.

The territory contiguous to Army camps and stations has generally included various cities and towns in which sanitation has often been neglected. These communities are dangerous to the health of the commands unless brought up to the same standard of sanitary regulation as is required for the camps. By statutory provisions their administration is charged to the local authorities, municipal or State, under the supervisory control of the United States Public Health Service. The Public Health Service has stationed officers of its service at the most important points, where they act in conjunction with the local authorities in the education of the local public and the initiation and maintenance of proper health activities. Frequently they are appointed deputy health officers and are given authority to enforce the local regulations which, in turn, are often drawn up by themselves. At those places where the Public Health Service has not been able to send representatives, the Army medical officers have been authorized to exercise a similar control. Such a system, by which the local health officials, the United States Public Health Service and the Army cooperate in the prevention of disease in both camps and surrounding territory, has resulted in the prompt notification of unusual health conditions, the control of epidemics, the sanitary regulation of eating and drinking places, public water, milk and other food supplies and their handlers, the prevention of flies and mosquitoes, the disposal of waste and excreta, the care of ice plants, the control of prostitution, the treatment of the venereally diseased, the prevention of illegal liquor dealing, etc.

13. SANITARY REGULATION.

A compilation of information on military hygiene and a summary of important sanitary measures to be employed in camps was made by the Division of Sanitation, and upon its recommendation was published by the War Department to the Army in the form of "Special Regulations 28." Compliance with its provisions is required by order. This is now a standard uniform guide for the sanitary control of all Army stations. Additional paragraphs are put in force as circumstances demand, the most important being paragraph 18½ on the subject of louse infestation. The efficiency of medical officers and of medical administration is estimated by special sanitary inspectors from the division who instruct and correct medical officers and report upon the sanitary administration of camps and stations in accordance with the requirements of these regulations.

14. COMMUNICABLE DISEASES IN GENERAL.

The prevention of diseases in military camps has long been considered one of the chief functions of the senior medical officer. Upon the organization of the first divisions this point was impressed upon the medical officers assigned as division surgeons. These officers have universally paid unusual attention to this subject, and it has been the subject of greatest concern to this division. At the outset of the mobilization, daily telegraphic reports of the incidence of meningitis and pneumonia were required by this office and weekly consolidated reports of all infectious diseases. In view of the fact that troops were brought into camps and cantonments before the completion of barrack construction and before there were adequate hospital facilities, in the light also of the overcrowding and insufficient clothing which have been indicated above, the Division of Sanitation points with a great deal of pride to the morbidity and mortality rates of the Army during the past year. The diseases causing the greatest number of deaths were those that are spread through the secretions from the respiratory tract—pneumonia, meningitis, measles, scarlet fever, and diphtheria. Together with tuberculosis these diseases caused 77 per cent of all deaths for the period from September 29, 1917, to March 29, 1918, during which period the weekly telegraphic reports have been carefully analyzed.

Measles was epidemic in nearly all the camps and appeared within a few weeks after mobilization, prevailing throughout the greater part of the winter of 1917. Pneumonia appeared in every camp and to an unusual degree in some. Empyema was a frequent complication, particularly in streptococcus pneumonia. Scarlet fever and meningitis appeared in epidemic form in certain camps, and occurred sporadically in all. Diphtheria was relatively infrequent and the deaths resulting were few.

Two points stand forth:

(1) The camps differed greatly in their disease and death rates.

(2) The high disease and death rates were almost exclusively confined to troops from the Southern States.

From the statistics studied it has been demonstrated very clearly that there has been a low death rate among northern and eastern troops and a high death rate among southern troops. The western troops occupy an intermediate position. There are a number of explanations for this.

(*a*) There is more acute respiratory disease among rural than among urban troops. Men from rural districts have not acquired immunity to these diseases in childhood as have the city men. Southern troops come largely from sparsely settled rural districts.

(*b*) Southern troops appear physically less robust than those from other sections, doubtless due in part to the widespread dissemination among them of such debilitating diseases as hookworm, malaria, and pellagra.

(*c*) Southern troops are relatively less familiar with the fundamental elements of personal hygiene and sanitation than are those from other sections of the country.

As protective measures against these diseases, the Army has followed the policy of frequent medical inspections of troops, isolation and quarantine of the sick, segregation of contacts, and determination of disease carriers and their isolation. The supreme importance of a natural protective immunity against disease is demonstrated by the failure to curb disease among Southern troops, where immunity did not exist and yet where the several measures of control referred to above were in effect.

The most promising measures for combating respiratory diseases—the diseases of crowded communities—is in the development of protective vaccines or sera and in the education of the soldier, or, better still, of the man before he becomes a soldier, in the elements of self-care, personal hygiene, and community sanitation. A vaccine for pneumonia has been prepared and is being used with promising results among volunteers.

The statements made above are an assurance to the public that the control of the group of respiratory diseases, now such a menace to the southern soldier, is by no means hopeless. With our present knowledge, strengthened by this study of our experience during the past year, the solution will, it is hoped, be found in continued study and experiments now going on. A board of medical officers has been appointed by the War Department to make an intensive study of pneumonia and important results are looked for.

Dust as a predisposing factor in the causation of respiratory diseases in certain camps has frequently been reported and has been considered of sufficient importance to justify recommendations for the oiling of roads and camp sites as a preventive measure. It has been the experience of medical officers of the Army that pneumonia has been unduly prevalent when there has been a large amount of dust at a station where troops were congregated. At one dusty camp in this country, two severe dust storms were followed on each occasion by a rapid increase of influenza, a great many cases of which were complicated by streptococcus pneumonia.

Contact infection by droplet transmission is of the greatest importance in the spread of the respiratory diseases, and detailed instructions to medical officers were issued by this division requiring the adoption of the cubicle system in the isolation wards and other wards of hospitals which were used for the treatment of respiratory infections. Cubicles were improvised by means of sheets suspended between the hospital beds, and aseptic methods, including face masks, were practiced by medical officers, nurses, and other attendants engaged in treating these patients. In barracks wide separation of the heads of the sleepers and free ventilation have been advocated as one measure to prevent droplet infection.

The occurrence of communicable diseases in camps and cantonments leads to an appreciation of the necessity of having in each camp a medical officer who could be free to devote his entire time and energy to the control of these diseases. This was in line with the modern methods of public health organizations in progressive communities and so the position of camp epidemiologist was established. It has been possible to select especially well-trained and well-informed officers for this duty and to assign them to all camps in which communicable diseases were at all frequent. Practically all of the large camps now have such an officer on the medical staff and these epidemiologists have been able to relieve division and camp surgeons of a large amount of important detail work, and to give intensive study to disease problems. Some division commanders and their surgeons have been so impressed with the utility of these specialists that they have developed for their division officers capable of carrying on the work after the departure of the division overseas. The study of epidemics has been further extended to certain States whose chief executives have requested the assignment of medical officers to duty with State boards of health whose special function is to act as liaison officer between the State officials and the camp authorities, keeping the latter informed of the prevalence of communicable diseases in communities from which men are being sent into the Army camps.

A most careful study of the incidence of infectious disease in the large camps has been made by the chief of the section of communicable diseases. This report will be published in full. The following abstract of a report is of much interest:

15. REPORT ON COMMUNICABLE DISEASES IN THE ARMY DURING THE WINTER MONTHS OF 1917 AND 1918.

[Statistics all from weekly telegraphic reports.]

The mobilization of such a large army as has been accomplished during the year is of special interest to the sanitarian and the epidemiologist. During the past 12 months more than a million men have been assembled in our camps, held together for intensive training, and sent over the sea. At present another million is being assembled and will go through a like process of training and join their comrades on the battlefields of France. These men have come from every section of the great country, from every class, without reference to previous social status, educational qualification, or personal habits. They have come from infected and uninfected localities. Immunes, susceptibles, infected have been brought together in the close contact which is a necessity in every military organization. To accomplish this great task without more or less spread of infection is an impossibility. Fortunately, advances in general sanitation, in water purification, and in garbage and sewage disposal, in protective measures against typhoid fever by vaccination, have largely eliminated from armies the intestinal diseases. If the morbidity from typhoid fever had been as great in the army during the months covered by this report as it was during the same time in certain civilian populations, there would have been more than 50,000 cases of this disease in the Army; whereas, in fact, there were less than 200 cases all told and less than 10 deaths in a million and a half of men. The unsanitary conditions as seen at Camp Alger and at Jacksonville and Chickamauga in 1898 do not exist in this country to-day.

A. DEATHS IN THE ARMY.

It was seen long before the assembly of troops was begun that the acute respiratory diseases would be the greatest factors in morbidity and mortality. With this in view the Surgeon General has insisted that at least 45 square feet of floor space and 500 cubic feet of air space should be allowed each soldier. It has been necessary, however, in some camps and during certain portions of the time to fall below these individual limits, and there have been camps in which the floor space per man has been reduced to two-thirds and even to one-half that mentioned above. Crowding is a military necessity, and by crowding we do not mean altogether the amount of space allowed in sleeping quarters. In fact, crowding during the hours of sleep, undesirable as it is, is less likely to aid in the dissemination of diseases, especially the acute respiratory diseases, than is crowding during the waking hours. During the day time men are coughing, sneezing, expectorating and otherwise discharging bacteria from their respiratory passages, and these are being inhaled by those in close contact with them. By these means the acute respiratory diseases are disseminated. Take, for instance, an assembly hall which accommodates several thousand. If every man in this hall, when all the seats are occupied, sits perfectly upright, the greatest distance possible between his nose and that of the man in front or behind him is 26 inches, while the distance between his nose and those of the men on each side of him is not more than 16 inches. With men thus placed and many of them coughing and sneezing it will be easily understood that the air is constantly filled with a spray laden with bacteria.

The death rate in the Army should be compared with that for the same age period in civil life. The comparisons should be made on the records for the same season of the year and so far as practicable for the same year. Through the courtesy of the health and vital statistics departments of certain States and cities, it has been possible to make this comparison. The greater number of enlisted men are between 21 and 31 years of age. The period corresponding to this available in civil statistics is the age from 20 to 29 years.

The following points should be borne in mind:

(*a*) The death rate of the group 20 to 29 years is lower than that of the present draft age 21 to 31.

(*b*) The death rate in these age groups is greater among males than among females. In fact, the death rate from pneumonia during this age is 40 per cent greater among males than among females.

(*c*) The Army includes more above than below the draft age.

In all these respects comparison is to the disadvantage of the Army. The following table gives a comparison of the annual death rate in the Army, with that of certain cities for the same period and for the same age group. The figures are based on weekly telegraphic reports.

TABLE NO. 146.—*Annual death rate per 1,000 in Army, compared with leading cities, United States (age 20 to 29 years; time, October, November, December, 1917, January, February, March, 1918).*

Place.	Death rate.	Place.	Death rate.
United States Army	9.1	New Orleans	10.4
New York City	5.5	Pittsburgh	6.2
St. Louis	5.5	Chicago	5.2

It is a striking fact that the death rates in the different camps show wide variation as is indicated in Table 147.

TABLE NO. 147.—*Annual death rates per 1,000 in United States Army within cantonment limits of United States, based on period Sept. 29, 1917, to Mar. 29, 1918.*

National Guard.	Rate.	National Army.	Rate.
Wheeler	28.3	Pike	30.7
Beauregard	25.4	Jackson	19.9
Bowie	23.1	Funston	16.3
Sevier	25.5	Travis	15.3
Cody	12.7	Lee	10.8
Doniphan	11.9	Dodge	9.1
Shelby	8.6	Taylor	9.0
Kearney	8.1	Gordon	7.8
Sheridan	2.8	Sherman	5.4
Hancock	2.6	Upton	5.3
Wadsworth	2.5	Custer	5.1
McClellan	2.4	Lewis	4.1
Logan	2.3	Meade	3.9
		Grant	3.8
		Devens	3.7
		Dix	2.9

It will be seen from Table 147 that five National Guard camps (Sheridan, Hancock, Wadsworth, McClellan, and Logan) have shown lower death rates than New York City, St. Louis, New Orleans, Pittsburgh, and Chicago for the age group 20 to 29 years. Two more National Guard camps (Shelby and Kearney) show lower death rates than New Orleans for this age group. Six National Army camps (Custer, Lewis, Meade, Grant, Devens, Dix) show lower death rates than any of the above mentioned cities. Two other National Guard camps (Sherman and Upton) are about on a level with New York City, St. Louis, and Chicago, and below Pittsburgh and New Orleans. Three more National Army camps (Dodge, Taylor, and Gordon) are below New Orleans. These facts demonstrate that camp life may be made as safe as that of some of our best health-guarded cities, and indeed may show a lower death rate in the corresponding age group. This is the goal which should be striven for. Of course the death rate among selected soldiers should be lower than among the population at large of the same age groups.

The great differences in death rates in the various camps have furnished a sanitary problem worthy of the most serious and detailed study. The following facts stand out most prominently:

(*a*) The location of the camp, whether in the South or in the North, the camp site, and the surroundings, have not been predominant factors in the causation of disease.

(*b*) Crowding, lack of clothing, fatigue, improper food, lack of heat or ventilation, and dust in camps have not played the most important rôle in morbidity or mortality.

(*c*) Men from rural communities are more susceptible to the acute respiratory diseases, and especially to pneumonia, than are those from urban life.

(*d*) On the whole the Southern soldier is much more susceptible to these diseases than his Northern comrade.

Pneumonia is an urban or a crowd disease in both civilian and military life. Our camps are the most crowded cities in our country, and consequently they furnish the highest rates for the respiratory diseases. The man who has lived in a densely populated area is more resistant to these diseases because he has been exposed to the same bacteria before, probably many times, and has acquired more or less immunity, or at least an increased resistance. For a converse reason, the man who has lived in a sparsely settled community is the more susceptible, because he has never before, or has not recently, harbored these bacteria. As previously stated, location of the camps has had nothing to do with the diseases prevalent in them, or at most, but a little to do therewith. There are certain geographical areas in which both good and bad camps are situated. However, when a map is made and the camps are placed not where they actually exist but each camp in the center of the population from which its troops came, then all the healthy camps are in one area. This area is included in lines drawn down the Atlantic coast from Maine to about the northern border of Maryland, to the Mississippi River, then north to the western end of Lake Superior. From this region came the healthiest soldiers in our camps, and they were the healthiest because they had greater resistance to those organisms which caused the acute respiratory diseases. There are possibly other factors involved in this problem. The Southern soldier is more susceptible largely because he has never, or but rarely, been brought in contact with the bacteria causing these diseases, and when contact does occur he displays but little resistance. Measles is much more common in the Southern States than in the northeastern district where we find the most robust soldiers coming from. The farther south one goes the more deadly is pneumonia. It is the more deadly because it is rare, and when introduced it falls upon virgin soil and the organism grows with greater intensity, and acquires marked virulence.

In the Civil War pneumonia was more prevalent and more fatal among Southern than among Northern troops. Among the former this disease annually affected 103 men out of every 1,000, while the corresponding rate for Federal white troops was 34, and the cases reported as acute bronchitis and catarrh numbered 415 per 1,000 among Southern troops as against 192 in the Union ranks. The death rate from pneumonia in certain divisions of the Confederate Army was 20.6 per 1,000, while in divisions of the Union Army, it was 7.8 per 1,000.

Measles prevailed in the Confederate Army, especially in new regiments, so greatly that it interfered with their organization. It so diminished the effectiveness of the troops and became so fatal in some camps that companies, battalions, and even whole regiments had to be disbanded for a time and the men sent home.

B. SPECIFIC CAUSES OF DEATH AMONG THE TROOPS.

As has already been indicated the diseases responsible for the great number of deaths in the Army during the winter of 1917 and 1918 are those generally known as the acute respiratory diseases. They are thus designated because they are transmitted from the respiratory organs of one man to the corresponding organs of another. While pneumonia, either primary or secondary to measles, and meningitis have exacted the greatest toll of life, they have not been the most potent factors in incapacitating troops, and in this respect they have been greatly surpassed by measles. The causes for admission to hospital or to quarters are stated in Table 148.

Table No. 148.—*Percentage relations of causes for admission to sick report in United States Army, within United States limits, based on period from Sept. 29, 1917, to Mar. 29, 1918 (weekly telegraphic report).*

	Per cent.		Per cent.
Causes other than disease	4.8	Malaria	0.018
Measles	7.3	Typhoid and paratyphoid	.019
Venereal	5.8	Diseases other than the above	75.5
Pneumonia	1.8		
Scarlet fever	.42	Total diseases	95.2
Meningitis	.21		

A. MEASLES.

This disease prevailed in epidemic form in all but three camps. These were Hancock, Wadsworth, and Upton, and were occupied almost solely by soldiers from Philadelphia, and New York. Measles appeared within a few weeks after the opening of the camps in September and persisted throughout the greater part of the winter. Camps Pike, Bowie, Wheeler, Sevier, Beauregard, and Jackson suffered most severely with this disease. At Beauregard the annual morbidity rate per 1,000 reached 2,700 during one week. A study of measles according to the nativity of the soldier shows that the United States may be divided into the following groups so far as susceptibility to this disease as displayed among soldiers is concerned. The first group, showing the greatest susceptibility to this disease, includes the following States: Texas, Florida, Alabama, Mississippi, Arkansas, and Tennessee. Although there are no records, Oklahoma probably comes in this group. Group No. 2 includes Louisiana, Georgia, and Kentucky. Group No. 3, includes North and South Carolina, Indiana, Missouri, Iowa, Wisconsin, Nebraska, and Kansas. Group No. 4 includes the rest of the United States.

Measles was present to an excessive degree in the same camps that experienced the most trouble from pneumonia. Southern troops suffered more severely from this disease. The mortality from uncomplicated measles is a minor factor when compared to that from pneumonia, either primary or secondary to measles.

B. PNEUMONIA.

Pneumonia, primary or secondary to measles, has caused more deaths than any other disease. It occurred in epidemic form in many camps, especially in those occupied by southern troops. The highest pneumonia morbidity rates were at Camps Bowie and Wheeler. The highest mortality rate from this disease was at Camp Pike.

Clinically, pneumonia has been reported as lobar and broncho. It is not easy in all cases to differentiate these forms. However, accepting the diagnosis numbers as reported, lobar pneumonia was the more prevalent in most camps. In some camps it is reported that the dominant form of pneumonia changed with the arrival of new troops. Most of the camps, not all, report that broncho pneumonia has been more fatal. At Camp Pike the case mortality is reported at 57 per cent in broncho and 35 per cent in lobar. At Camp Cody the cases showed slightly higher rate in the lobar form. It is generally agreed that broncho-pneumonia is more frequently a secondary infection.

A more important matter is the prevalence of a pneumonia in which the streptococcus hemolyticus appears as the causative agent. This organism is reported as causing both lobar and broncho pneumonia, and the pneumonia caused by it appears to be more frequently complicated with empyema and more fatal than that due to the pneumococcus.

In order to prevent the spread of pneumonia, as well as other communicable diseases, each patient in hospital has been inclosed in a cubicle formed by hanging sheets on frames between the beds. In addition to this all patients carried to hospitals, and while out of cubicle in hospitals, wear masks consisting of three or four thicknesses of gauze. These measures have undoubtedly been of value and should be continued hereafter. In fact there is no reason why shelter tents should not be used for the formation of cubicles in barracks.

C. MENINGITIS.

This disease has appeared in every camp during the six winter months of 1917–18. However, it has been epidemic only in three camps, Jackson, Beauregard, and Funston. Indeed, it has been epidemic only in those camps where soldiers have been drawn from areas in which this disease has been endemic.

Meningitis, next to pneumonia, primary or secondary to measles, has been the most serious disease that the Medical Corps of the Army has had to contend with. It is serious by reason of its high fatality, and also because this of all diseases shows the greatest excess over its prevalence in civilian communities. It is estimated that meningitis has been more prevalent among the soldiers than it has been in any part of the United States during the same period, and taking the average in the Army and the average in the civilian communities, meningitis has been 45 times as prevalent in the Army as in civilian life. This disease is widely scattered over our country, and the draft acts as a dragnet, bringing those who have been exposed and those who are carriers to our camps where they come in contact with highly susceptible individuals, thus spreading the disease. It is unfortunate that drafted men from localities in which meningitis is known to exist can not be kept at home until shown to be free from infection.

D. SCARLET FEVER.

This disease has been most manifest at Camps Pike, Lewis, Kearney, Sherman, Dodge, and Grant. However, its great prevalence at Camp Pike stands out distinctly. The rate at this camp is nearly twice that of the second camp. Scarlet fever was more prevalent in the National Army than in the National Guard camps. It seems probable that this fact is attributable to the presence of the disease in the particular localities from which troops have been drawn. This accounts for the disease in both Camp Kearney and Camp Lewis, which receives men from the same general localities. The greater prevalence of scarlet fever in the National Army as compared with the National Guard may be explained by the later assembly of the National Army and by the continual additions to these camps from civilian life.

E. DIPHTHERIA.

This disease occurred in only 7 out of 29 camps. Here, again, Camp Pike, which has a bad reputation in many things, leads the list. Camps Funston, Dodge, Cody, and Custer come next in order. On account of the specific treatment, diphtheria has not caused a large number of deaths.

16. DIVISION OF MEDICAL RECORDS.

Attached to the Sanitary Division for administrative purposes is also the Division of Medical Records. This division, as its name implies, handles all the medical records of enlisted men and officers serving either in this country or abroad. As was to be expected, it has been expanded very greatly during the present year. All the medical records are filed as promptly as possible, so that all inquiries for information coming through the authorized channels may be answered with as little delay as possible.

After the Civil War there was a great deal of confusion and delay in settling claims, for the medical records were imperfect and it was difficult to obtain information from them. Untold millions of dollars will be involved in the settlement of the various claims that will be made against the Government, all of which must be settled by the evidence from these records.

This office receives also the daily reports of hospitals from "over there." This daily report is a recent innovation. They are arranged as soon as received, so that fairly prompt information can be furnished to all relatives and friends regarding the character of wounds or causes of the deaths in the American Expeditionary Force.

The daily cablegrams of casualties are also carded and from these are prepared weekly statements for the Chief of Staff. It is from these statements that the current information relative to all casualties is furnished to the Secretary of War and other officials.

During the past few months it was found necessary on account of the greatly enlarged Army to change the entire system of tabulating statistics in this division. The old method of tabulating by hand has now been replaced by a modern system of perforated cards, which are sorted and tabulated by electric machines. It will thus be possible to publish from year to year the health statistics of the Army in the annual report.

The work has been so arranged that after the war is concluded the work of preparing the statistics for the "Medical and Surgical History of the War" will be a continuation of the work that is being carried on for the preparation of the statistical tables for the Surgeon General's report. Thus it will be possible to complete the statistical work for the "Medical and Surgical History of the War" within a comparatively short time, instead of after a number of years as was the case after the Civil War. Few publications have been of greater value to the medical profession in this country and abroad than the "Medical and Surgical History of the War." It is especially desirable that the valuable medical and surgical material of this war should be available for the use of the entire medical profession as soon as practicable.

17. GENERAL REMARKS ON SANITATION BY DEPARTMENT SURGEONS.

(Extracts from reports.)

A. SOUTHEASTERN DEPARTMENT.

During the period May 1 to July 20 the nine National Guard divisional camps and the three National Army cantonments within the geographical limits of this department were subject to the authority of the department commander. General Orders No. 96, War Department, July 20, divorced these camps from departmental authority in all matters save supply. This condition continued until General Orders No. 96 were modified on October 15, at which time the divisional camps and cantonments were made entirely independent of these headquarters.

On May 1 the department surgeon's office made contact with sanitary detachments, Regular and National Guards, throughout the entire department, and a schedule of intensive instruction for sanitary troops was prepared and issued. Tentative selection of main and subsidiary medical supply depots and a department laboratory was made. Correspondence was entered into with the Surgeon General's Office over the proposed location of camps and cantonments, and the form and number of medical establishments to be constructed therein. Numerous Red Cross companies and base hospitals were organized and enlisted in the Medical Enlisted Reserve Corps to await the pleasure of the War Department for assignment.

B. EASTERN DEPARTMENT.

The surgeon reports that since the declaration of war the hospital has performed many functions not required in peace times. Over 2,000 candidates for training camps were examined. From 1,000 to 2,000 protective inoculations have been given monthly. For two months an overseas casual camp was administered. Men of special qualifications were furnished units and promptly replaced by searching out recruits from New York or by training men already in the detachment. The hospital acted as a clearing office for the militia and casual offices. It was an unofficial consultant and advisor for medical men, organizations, and civilians on all sorts of topics. The surgeon was called upon for lectures to college students, special courses in military hygiene to senior classes of medical schools, medical societies, and an association of medical reserve officers. In addition, militia organizations were examined for muster in, and work was continued in the office on many occasions until after midnight. On the whole, officers and men worked loyally and uncomplainingly and exhibited the proper spirit and morale under the trying and unusual conditions imposed.

Allentown, Pa., United States Army Ambulance Service.—This camp is under the direction of Col. Elbert E. Persons, Army Ambulance Service. It began on June 1, 1917. The average number of men in the command was approximately 3,200.

The commanding officer reports that so far as known this is the only camp in the United States in which the men are not messed by organizations. On account of local conditions a general mess was adopted at this camp on July 1, 1917. There has been no sickness of a considerable number of men at one time, which may be attributed to improper food or insanitary preparation of food. The men have been well fed and the mess saved and declared a dividend from the company fund aggregating $10 per capita for the period covered. The health of the command has been excellent.

C. WESTERN DEPARTMENT.

The hasty and superficial examinations given by inexperienced and indifferent medical examiners to applicants for enlistment, immediately following the declaration of war, is reflected in the enormous increase in discharges for disability existing prior to enlistment. These do not include the large number of men of National Guard regiments who were discharged for disabilities detected by the medical examiners at the time of muster of their organizations into Federal service. Under War Department instructions mustering officers were authorized to discharge, without prior reference to these headquarters, cases of physical disability detected by them at muster-in examinations. The number so discharged indicated that recruits enlisted in the State National Guard regiments were not required to come up to the standard exacted for the Regular service. As a result many National Guard organizations had an actual effectiveness of only about 75 per cent of their paper strength. During the past three months boards, consisting of specialists in tuberculosis and cardiovascular diseases, have been sent to the majority of posts in the department for the examination of troops for these diseases. These boards are still engaged on this duty and the result of their work already accomplished has been submitted to the Surgeon General of the Army in the shape of a report from each post examined. The prompt elimination of these physical defectives, and particularly the tubercular subjects, will doubtless result in the saving to the Government of millions for pensions and for days lost in hospital, had these defective soldiers not been promptly discovered and eliminated. At the outset it appeared to be the intention of the War Department to examine only those troops at stations known as "organization camps." Shortly after my arrival at these headquarters, however, I became convinced that these examinations should not be limited to the several large stations, but should be general throughout the entire department, as the majority of the troops were men who had enlisted subsequent to the declaration of war, and had received a most hasty and superficial examination. The result obtained has confirmed my opinion, and the comparatively small expense for mileage is more than offset by the assurance that the men in organizations have been given a thorough physical examination and found qualified for actual field service, without the liability of breakdown. During the calendar year there were 1,399 discharges for disability, of which 195 were in line of duty and 1,204 not in line of duty.

The United States becomes responsible for the medical attendance and supplies of the National Guard organizations from the date on which they report at their company rendezvous. No sooner had these organizations so reported than there appeared to develop a mania for purchase of drugs, hire of civilian physicians, and treatment of officers and soldiers in civilian hospitals. To a certain extent this procedure was necessary and permissible under paragraph 1476, Army Regulations, particularly for those organizations guarding tunnels, bridges, and public utilities, frequently scattered in small detachments. The idea seemed to prevail among the National Guard officers, medical and line, that as the United States was responsible for the bills there need be no limit to the expenditures.

Accounts were sent to this office which indicated that an earnest effort had been made to purchase at least one item of the varied stock of drug stores, or to place men of every organization in some civilian hospital, or under the care of a civilian physician. Needless to say, not only these but all accounts have been closely scrutinized and nothing left undone to safeguard the interests of the Government. In spite o numerous letters on the subject, settlement of these accounts has been considerably delayed and has caused an almost interminable correspondence by reason of the failure of the officers responsible for the purchase or service to render vouchers immediately on the conclusion of such purchase or service. The accounts, even when rendered, are habitually in such form as to render it necessary for this office to prepare the voucher for signature of the creditor and certificate of the officer responsible, the latter by that time being in France or at some eastern embarkation point.

D. CENTRAL DEPARTMENT.

The mean strength of command for the year, as reported on returns of the Medical Department, was 19,899.67. The total admissions to sick report from disease and injury numbered 14,567, with a ratio of 732.022 per 1,000. A total of 131,723 days were lost by sickness, making a daily noneffective from all causes of 18.135 per 1,000.

On May 8, when the first officers' training camp was to be opened at Fort Snelling, Minn., the Medical Department personnel consisted of two officers, Medical Corps, one lieutenant, Medical Reserve Corps, one master hospital sergeant, eight privates and privates, first class, Medical Department, a shell of a hospital, with buildings, in only fair condition.

A partial regiment of National Guard was camped on the reservation at Fort Snelling. On May 15 enough candidates had been examined physically to start in training 2,500 students of the officers' training school. A hospital had been put into running capacity, requisitions submitted for 300 beds, barrack, kitchen, and administrative features prepared for a recruit company of 200 hospital department men, and sanitary management completed for a command of a training camp and four regiments of Infantry and a regiment of Artillery.

One of the first and most successful acquisitions to effective work in meeting the emergency of sudden expansion with only new and untrained men to work with, was 16 trained nurses (female) under a head nurse, Miss Sophia Burns, of the Army Nurse Corps.

New medical men direct from civil practice found their places as best they could under Army conditions strange to them, and soon came to appreciate the advantages to be derived from a practical course of schooling. This was instituted in accordance with circular letter, Surgeon General's Office, dated May 14, 1917, and was carried through in every detail with great credit to all concerned.

Considering the frequent changes in both the commissioned and enlisted medical personnel, the fact that this personnel was largely composed of men new to the service and the vast amount of work thrust upon them, their services have been most gratifying. This degree of efficiency has been due to the schedule of intensive training prescribed by the Surgeon General May 14, 1917, which has been carried out in this department, to the similar schedule of instructions in force in the medical officers' training camps, and the intellectual caliber of the men entering this branch of the service.

E. SOUTHERN DEPARTMENT.

In considering the operations of the Medical Department of the Southern Department for the calendar year 1917, the special condition that pertained during the year will first be briefly enumerated in order that a proper understanding of the situation be called to mind.

During 1916 practically the entire available military force of the United States, including the militia of practically all the States, had been mobilized in this department in connection with the Mexican border troubles. These forces, numbering altogether 160,000 men in December, 1916, were gradually moved out of the department, the main homeward-bound movement of the militia beginning January 2, 1917. At the end of the month there were 50,000 Regular troops and 70,000 State troops of the States comprising the department. The Regular troops in this department maintained a fairly constant strength throughout the year, the average being 57,408. On April 5, 1917, just prior to the declaration of war, the State troops were again called into the Federal service and at the end of April these troops in the Southern Department numbered 5,740. This was about the average number for the remainder of the time during which the militia was under department control with the exception of the month of August, when the number increased to 17,664. This increase is explained by the fact that the State troops were assembling in Southern Department territory for the National Guard divisional camps which opened during September and October, after which time the militia passed out of the department control by the organization of divisions. There are five National Guard divisional training camps within the territory comprising the Southern Department.

As previously stated, the strength of command in the Southern Department for the year 1917 has fluctuated widely, from a maximum of 119,178, January 31, 1917, to a minimum of 51,096, March 31, 1917; again reaching a high figure of 85,242, August 31, 1917. These figures include both Regular Army and National Guard officers and enlisted men.

For the Regular Army troops, the number in the department averaged 57,408 officers and enlisted men, the figures ranging from 48,492 in May to 67,578 in August. These figures omit the large number of men of the aviation section, Signal Corps, in training at Kelly Field. Since October 5, when the number of men at this station was 11,000 and had in December increased to approximately 32,000, reports of sick and wounded from this station have not been forwarded through this department. Attention is called to this for the reason that a large part of the work at Base Hospital No. 1, Fort Sam Houston, Tex., is received from this aviation station. At Kelly Field itself, there is only a small camp hospital, not equipped for handling serious cases.

Again, during the latter part of the year a considerable number of cases, about 2,200, were treated at Base Hospital No. 1, Fort Sam Houston, belonging to the National Army cantonment at Camp Travis. This was due to the fact that the base hospital at that camp was not ready for two months after the camp itself was put into service. These cases were reported direct to Camp Travis for transmission to the Surgeon General and do not appear on the weekly reports of this department, but during October, November, and December they occasioned a very material part of the work of that hospital. Figures are not available to show the number of men in this territory contributing to Base Hospital No. 1, but besides the department proper there is, as above mentioned, Kelly Field, Camp Travis, and the officers' training camp at Leon Springs, Tex., which at times numbered 4,000 men.

F. FORT OGLETHORPE, GA.

The middle of May marked the beginning of the expansion of military activities in Chickamauga Park, Ga., the personnel of troops representing about two-thirds recruits and one-third seasoned soldiers. Until the advent of cold weather, clothing was sufficient, but since then a lack of sufficient woolen clothing was felt. This condition has now been remedied except for the pressing need for heavy woolen blouses and breeches.

In the formative period of the camp, tents served as shelter until rough, unceiled, wooden one-story buildings were constructed. As cold weather approached, these buildings were double floored, side walls were ceiled inside and a layer of beaver board made to form a ceiling overhead and an adequate number of stoves installed. An insufficient supply of coal has made the use of wood necessary for heating purposes, which latter for the most part has been green and of poor quality.

The health of the experienced soldiers has been very good. As might have been expected among so many recruits from rural districts, measles, mumps, pneumonia, a few cases of scarlet fever, and diphtheria appeared. Fourteen cases of cerebrospinal meningitis occurred, with 3 deaths. The outbreak of mumps reached its highest point about the middle of December, when 420 cases were under treatment.

18. GENERAL MEDICAL SERVICE BY DEPARTMENT SURGEONS.

A. SOUTHERN DEPARTMENT.

In the case of the Regular Army the incidence of disease for the first three months of 1917 averaged between 22 and 30 per week per 1,000. During April and May this figure increased to about 40 per 1,000, owing to the numerous enlistments, but since the middle of June, when the weekly rate was 36 per 1,000, the rate has gradually decreased till the end of the year, when rates of 15 to 18 per 1,000 have been maintained. These favorable rates, however, unfortunately have not continued into the present year, owing to the epidemics of measles, pneumonia, etc.

With a total strength of command fluctuating widely from week to week, and month to month, as has been the case with the National Guard troops in this department, it is difficult if not impossible to determine reliable morbidity rates. However, there seems to be a tendency to a rate which is slightly higher than in the regular forces.

Including measles with the respiratory disease and taking the total of such diseases with influenza, pneumonia, and tonsillitis, we have a group of diseases which comprises one-third of all the admissions on sick report of the Regular Army and National Army for the year and over one-half of similar cases of the militia.

B. CENTRAL DEPARTMENT.

Tuberculosis cases were very prevalent, there being 71 cases at Fort Benjamin Harrison, Ind.; 44 cases at Fort Riley, Kans.; 43 cases at Fort Des Moines, Iowa; 24 cases at Fort Sheridan, Ill.; 13 cases at Fort Crook, Nebr.; 11 cases at Fort Snelling, Minn.; 10 cases at Fort Leavenworth, Kans.; 3 cases at Fort Brady, Mich.; and 1 case at Fort Wayne, Mich.

Fort Benjamin Harrison, Ind.—The amount of sickness has been unusually small and the mortality extremely low. There has been remarkable immunity from diarrhea, dysentery, gastrointestinal and other diseases of the digestive organs. This condition is evidently due to excellent quality of food and extremely favorable sanitary condition of post. Military control of restaurants, lunch stands, etc., contiguous to post has contributed greatly to this result. There were a few cases of smallpox (mild type) during the early part of the year, but these cases occurred only among those who were recently enlisted and before a successful vaccination could be effected. There have been only a few cases of cerebrospinal meningitis. Sporadic cases of diphtheria have occurred, but they were promptly brought under control by locating the carriers and immediately isolating and immunizing them with antitoxin. A mild epidemic of measles has prevailed with practical elimination of pneumonia as a complication. A mild epidemic of scarlet fever at one time threatened the Tenth Infantry by infection of 10 or 12 men. Prompt isolation of Company B and the maintaining of a most successful quarantine promptly brought the threatened epidemic to an end.

Fort Leavenworth, Kans.—There were several outbreaks of infectious diseases but the active cases have been effectively isolated and the threatened epidemic killed in the shell. The civil population of the post has been singularly free from diseases, no case worthy of note being on record. The inundation of transient units and individuals comprising the training camps for officers and provisional officers and recruits for depot companies contributed largely to the percentage of sick and to the variety of diseases.

Measles and mumps have existed continuously since July and are at present on the decline. Meningitis, diphtheria, and scarlet fever existed sporadically, a few cases being constantly present, and nearly all contracted before arrival at post. A few cases of smallpox in nonvaccinated cases, contracted from outside sources and prior to arrival in post, developed; also one case of typhoid fever that had received first dose only toward immunization prior to attack.

Fort Snelling, Minn.—There has not been a single failure in enteroenterostomies, herniotomies, appendectomies, gall bladder and kidney operations, bladder and genito-urinary work, bone and joint surgery, head and mouth work, and in plastic surgery. There have been 233 operations performed since June 16, 1917. The department of nose, ear, and throat and that of internist have a record of 31 pneumonias and only 1 death; 4 meningitis cases and but 1 death, due in this case to other causes.

The various organizations, aggregating 17,000 men, have been examined exhaustively for psychoneuroses and tuberculosis, and the hospital at this station has attended to the sick and to the military medical training of the troops in Wisconsin, North Dakota, and Iowa, with an average constant sick of about 132. The prevailing diseases have been for the summer months; mild gastrointestinal disorders, with occasional ptomaine attacks which were attributed largely to ice cream, hence this commodity was cut out entirely and not allowed to be brought upon the post, with certainly a marked diminution of autointoxication ailments. Venereal diseases steadily increased, but were held in check to a moderate extent by an effort only partially effective in enforcing the usual methods of prophylaxis and the provisions of general order 17, 1912.

With the advance of cold weather pulmonary affections, mumps, and measles appeared more and more frequently on the sick report, with occasional diphtheria and meningitis cases. To control these diseases more effectually effort was made to pick out carriers from the companies and isolate them within the barracks. When the epidemic of mumps, measles, and pneumonia assumed alarming proportions, the barracks being badly overcrowded, a vigorous effort was made, with the hearty cooperation of the commanding officer, to have the company officers daily pick out, and call out, all men showing or complaining of any symptoms of colds or other affections, remove them from among the well men and segregate them in one part of the barracks. These so isolated were then removed, the ones who recovered (this without hospital treatment), with the result that soon all new cases originated in these separated sections only, and there was a rapid reduction of all these affections and the complete eradication of measles and pneumonia from the troops' barracks.

From this time on sporadic cases of mumps only have occurred. With this diminution of increment to the sick report the cases received were held in the hospital beyond the time that their condition would seem to require, in order to further reduce the chance of infection. As a consequence marked temporary rise in noneffective rate to almost 60 per 1,000 in December ensued. Prior to this the noneffective rate had never exceeded 11 or 12 per 1,000, the rate for the year reaching 15 plus. To prevent mouth-to-mouth infection every bed in the barracks had its mosquito-bar rods in place, and from the left side of these rods each man suspended his shelter half so that it hung along the side of his bed. Thus was there placed between each sleeping man a suspended screen to act as a mechanical barrier to droplet infections. This has not been in effect long enough to demonstrate results. In the hospital suspended sheets replaced the shelter halves of the barracks.

C. EASTERN DEPARTMENT.

Fort Jay, N. Y.—During the fall of 1917 an epidemic of measles occurred at this post. The admission rate during the period was 337.28 per 1,000 per year. There has been a marked decrease of venereal diseases for the past year. Most of these cases were contracted prior to arrival at the post.

Madison Barracks, N. Y.—The surgeon reported that during September, October, and November there were 123 cases of measles, 75 mumps, and 11 diphtheria at the post, and that it is probable that the crowded conditions of the barracks had much to do with the extension of the epidemics of measles and mumps. He reports one case of spinal meningitis occurring on September 29, the patient dying within 24 hours.

Fort Monroe, Va.—The surgeon reports 19 cases of pneumonia at the post during the year, one being acute lobar pneumonia and 5 acute pneumonic tuberculosis in negroes. There were 3 deaths and 1 case of permanent blindness from wood-alcohol poisoning.

Plattsburg Barracks, N. Y.—The surgeon reports no epidemic disease occurring during the year with the exception of acute epidemic conjunctivitis (pink eye), caused by the Koch-Weeks bacillus. A very large number of cases of this disease occurred during the first officers' training camp, which was ascribed to the use of the common washbasin. On the discontinuation of the use of the common basin for washing the epidemic gradually disappeared.

One case of acute anterior poliomyelitis was also reported as occurring in October during the second officers' training camp, in a candidate 25 years of age who had been exposed to severe weather conditions by being in the trenches all night. He was evidently a carrier of the disease, and owing to exposure his resistance to development of the disease was lowered. He had not been away from his station and the disease was nonexistent in this locality.

Allentown, Pa., United States Army Ambulance Service.—The commanding officer, United States Army Ambulance Service, reports that the work of the camp hospital was conducted in tents through the months of June, July, August, September, and October, and the more serious operative cases were treated at the Allentown Hospital. This hospital is reported to have a splendid management, excellent facilities and plumbing, and on account of its proximity to the camp has rendered very valuable service.

During November and December sick call, dispensary, surgical dressings, and infirmary have occupied temporary quarters in the basement of the Allentown Hospital, while premanent infirmary building was being erected. The sick rate of the camp has been comparatively low, namely 17.52 per 1,000 of strength constantl noneffective.

19. SANITATION, BY DEPARTMENTAL SURGEONS.

A. SOUTHEASTERN DEPARTMENT.

During the period May 1 to June 30 no morbidity of moment arose, the main movement of sick being malaria, arising from detachments guarding public utilities, du to inadequate housing facilities. To relieve this condition, due to lack of screening quining prophylaxis was directed and carried out, with marked result.

The following activities were of note: Inspection of proposed camp sites Savannah Ga., and Charlotte, N. C., and recommendation for rejection of the first and acceptanc of the second. Publication and issue of General Sanitary Code to all troops within th department. The selection of a large main medical supply depot at Atlanta, Ga Due to an epidemic of typhoid in the States of North Carolina and Tennessee intensiv inoculation of all National Guard troops in those States. Upon muster into Federa service of National Guard organizations immediate preparation for their sanitar supplies and organizations of detachments and units in conformity with existin tables of organization. Organization and supply of new Regular regiments in thi department. Plans were entered into with the Surgeon General's Office and wit the authority of the department commander for the use of the post hospitals, certai barracks and buildings of the posts of Forts McPherson, Oglethorpe, and Logan I Roots, as a nucleus for a base hospital at each of these points.

In compliance with General Orders 96, War Department, divisional medical suppl officers were assigned by the Surgeon General to each of the 12 divisional camps, an without requisition a complete base hospital and initial medical equipment for a troops, for three months in advance, ordered issued and sent by express. Sanitar inspectors were assigned to each camp during the period of construction, with orde to make a complete survey of the camp site and maneuver terrain and eradicate a unsanitary conditions. With the exception of the cantonment at Camp Pike and Camp Jackson, little of moment was found requiring attention from a sanitary standpoint.

The large number of workmen gathered at the camps and cantonments from all sections of the country would naturally have given rise to typhoid and smallpox, and to obviate these dangers the sanitary inspectors at such points were ordered to complete vaccination of all men. The results have fully met expectations.

On May 14 a circular was issued directing the administration of oil of chenopodium for the eradication of hookworm, the procedure suggested being the administration of one 5-minim globule at 7 a. m. on a fasting stomach, a second at 10 a. m., and a purgative of Epsom salts or castor oil at noon.

B. SOUTHERN DEPARTMENT.

Fort Sam Houston, Tex.—Sanitary inspections of camps was maintained throughout the year and in general conditions have been satisfactory.

C. CENTRAL DEPARTMENT.

With the calling into the Federal service of the National Guard and organization of officers' training camps it became necessary to expand many of the military posts in this department to several times their normal capacity and to lay out many new camp sites. In connection with these expansions the question of water supply, disposal of sewage, garbage, bathing facilities, etc., all had to be solved, while at the same time the task of conducting the physical examination of all troops entering the Federal service and their immunization against small pox and typhoid fever were thrust upon the medical personnel.

Fort Benjamin Harrison, Ind.—The sanitary conditions have at all times been excellent. This is no doubt due to the efficient administration of the medical officers in charge of the medical officers' training camp, the sanitation of the post being in charge of selected officers for this work for the period of about three months. Their work has been thoroughly efficient and it has been the endeavor to maintain a high standard of sanitation. Unsanitary conditions resulting from overcrowding in quarters, personal uncleanliness from neglect of bathing, improperly cooked food, etc., have been promptly corrected through action taken on reports of inspection. In the summer, examination of various swimming pools, proper analyses of water, noting the quantity, quality, drainage, and source of supply, number of bathers, care of pools, etc., and report of conditions in general were made to the post commander. This precaution evidently prevented many diseases and especially those of microbic origin, affecting the eyes and ears. General sanitation of post excellent, disposal of sewage, stable manure, kitchen garbage, etc., ample. The installation of septic tanks, and provisions for an adequate water and milk supply have been noted in previous sanitary reports.

D. EASTERN DEPARTMENT.

Fort Hamilton, N. Y.—An active campaign was carried on at this post during the year against the breeding of flies.

Fort Totten, N. Y.—Measures taken to decrease the number of mosquitoes have only been partially successful. This post is situated on a point jutting into Little Neck Bay on Long Island Sound, an area of about 30 acres being between it and the mainland. This area is salt marsh and stagnant water and always has been a source of trouble with regard to the breeding of mosquitoes. Drainage seems to be impossible.

A new system of sewerage and sewage disposal is about completed. The plumbing throughout the post is old and frequent repairs are necessary. The guardhouse is inadequate under present conditions and recommendations have been made to enlarge it. The incinerator used for the disposal of waste is old, out of date in design, and practically unserviceable. The surgeon has recommended that a new incinerator be installed.

20. HOUSING AND VENTILATION, BY DEPARTMENTAL SURGEONS.

A. EASTERN DEPARTMENT.

Camp American University, Washington, D. C.—The camp commander reports that there are 400 more men in the camp than the maximum allowance for the space available. He stated that the Chief of Engineers was requested to make further efforts to get money for building an engineer cantonment, that such efforts were being continually made, but so far without success. However, the number of troops in this camp varies on account of the departure of troops for overseas.

Fort Hamilton, N. Y.—Lack of suitable accommodations for the National Guard troops which arrived in August was a troublesome factor which has been remedied by the construction of cantonments for mess halls.

Camp A. L. Mills, N. Y.—The commanding general, Forty-first Division reported that eight men were sleeping in each pyramidal tent, which did not permit of 500 cubic feet of air space for each man, nor of the separation of 5 feet between the heads of occupants of bunks, and that orders had been put in effect that the top of half the door space of tents be open all the time except during rainfall.

Fort Terry, N. Y.—Overcrowding in barracks is reported. In December, with the formation of the batteries here for overseas duty, and the influx of draft men sent to fill up these batteries, the barracks originally built for 109 men were crowded to hold 235 men forming these batteries. The cantonments ordered to be erected at this post were started in December. When these are completed it will relieve the overcrowding.

Fort Washington, Md.—The surgeon reports that owing to the number of recruits and drafted men received at the post, there are not sufficient barracks to house them properly it having been necessary to use the gymnasium as sleeping quarters for the troops. He recommends that additional cantonments be built at once. The commanding officer, Coast Defenses of the Potomac, has been directed to take the necessary steps to secure adequate sleeping accommodations for the troops at Fort Washington.

Fort Wood, N. Y.—The present barracks are reported to be greatly overcrowded, men sleeping in the schoolroom, gymnasium, and basement of the barracks. The construction of cantonments to accommodate 500 men had been recommended and the Quartermaster General has recently had a representative of his office at Fort Wood to investigate and report on the matter.

B. SOUTHERN DEPARTMENT.

Fort Sam Houston, Tex.—Tents are gradually being replaced by barracks or tent frames erected with board sides. These are warmer for winter use than barracks unless the frame structure of such barracks is covered with some sort of sheathing material. In this case the question of ventilation of both requires the same attention. Without such sheathing the problem of heating barracks is extremely difficult, and the quantity of fuel required is excessive and does not accomplish its purposes. Patients in hospitals so constructed, who could otherwise be up and around, must stay in bed to keep warm.

In some of the border stations. adobe houses have been constructed by the men and make most comfortable quarters for the climate where dust storms are a frequent cause of great annoyance.

Where tents are in use for quarters, overcrowding and lack of ventilation are the most constant cause of trouble. The importance of this danger is now especially emphasized by recent investigation into the etiology of the respiratory diseases, including, in this group, measles and tonsillitis. Frame barracks except for overcrowding are not in most cases such great offenders in this regard, as the cracks between the boards allow almost too free ventilation in windy weather, but with tents the tendency to close all ventilating openings is ever present and required constant watchfulness on the part of the sanitary officers.

In November orders were issued restricting the number of men in barracks and tents so that not less than 500 cubic feet of air space and 40 square feet of floor space was provided for each man with at least 5 feet between bunks. Later instructions were issued to alternate the heads and feet of men as they slept, so that an even greater distance separated their heads and less danger of "droplet" infection existed.

C. FORT M'PHERSON, GA.

Remarks of post surgeon, Fort McPherson, Ga.:

When the plans for the cantonment barracks were first received at this post, I carefully examined them and informed the commanding officer that the allowance of cubic air space was entirely too small, and recommended that before the buildings were put up he communicate my objections to the War Department. The commanding officer did not approve of this recommendation, on the ground that the plans were sent from Washington and that he had no other recourse but to put the building up. I informed him that I would make a sanitary report immediately when they were occupied.

On opening up the training camp (reserve officers of the line) and before many of the candidates had arrived I made a thorough inspection of these buildings and their contents, and made the following special report to the commanding officer:

* * * "The examination of the first two or three barracks now occupied by applicants for the officers' training camp shows a very unsanitary condition of affairs. Without exception, all beds are touching each other. Aside from the lack of initial air space, such a condition of affairs, in which this close and intimate association of large bodies of men occur, can not but end disastrously in an epidemic of various infectious diseases, if our experience in the past is of any value. I recommend that sufficient additional barracks be built at once, in such quantity as to permit at least the space of a bunk between each occupied bunk. This, it seems to me, on sanitary grounds, should be the minimum of floor space."

The department surgeon was able to obtain from the department commander additional buildings, and in the meantime all candidates over and above one for every 600 cubic feet were put in tents. The wisdom of this was manifested in the fact that the training camp at Fort McPherson was exceptionally free from contagious diseases, nothing more than a few cases of conjunctivitis having occurred.

The sewage disposal plant was much overworked when the training camp was in full swing, resulting in foulness. Although recommendations for the abatement of the nuisance were made, the matter was not taken up until after the arrival of a special sanitary inspector from the Surgeon General's Office in August. An allotment has now been made which it is believed will correct all deficiencies.

United States Hospital No. 6 is excellently equipped.

D. SOUTHEASTERN DEPARTMENT.

On September 13 recommendation was made to the Surgeon General for the installation of the Sayville water heater, or equivalent, for camps and cantonments, reminding the Surgeon General that by the middle of October the change of temperature would be such that southern troops would refrain from using cold-water showers, and that to insure physical comfort and cleanliness of these troops, the necessity for installation of such water heaters was essential, at the rate of one to each thousand men. Paragraph 4 of that recommendation stated that "this recommendation is made at this time in view of the difficulty the Quartermaster's Department has encountered in securing plumbing facilities, and as each of these heaters can be made in the course of a day by local talent, by the use of one 30-gallon boiler and several strings of pipe and knuckles, it would appear more satisfactory to have camp quartermasters procure the necessary articles and construct one for each 1,000 men, so that they will be available when the demand arises, and a long wait will not have to be made on the pleasure of congested railways."

The following letter to The Adjutant General of the Army, with reference to the advisability of providing tent floors at all National Guard divisional camps, was written by the department surgeon:

"It is recommended that the decision not to provide tent floors for the National Guard divisional camps be reconsidered, and that authority for the purchase of the necessary lumber be granted to constructing quartermasters.

"The labor of constructing tent floors can be performed in part by troops of the advance detachments, and completed when the organizations arrive. The total cost per tent should not exceed $4 to $5, or approximately 50 cents per man, and the saving to equipment and clothing and the certainty of a neat and orderly arrangement within tents would, it is believed, amply justify the expense, even without taking into consideration the comfort and contentment and physical well-being of the troops.

"I wish to invite attention, also, to the evident fact that the saving made on material for tent floors will be more than counterbalanced by the increase in sick rate, with a corresponding reduction in efficiency. As the deficiency in canvas will cause necessary overcrowding, it is thought the part of wisdom to take every precaution to minimize the danger of communicable diseases, and tent floors being susceptible to mechanical cleaning, will go far toward the reduction of such diseases as can be acquired from men in close contact who can not be so disciplined that they will not expectorate on the floor, as they invariably do in unfloored tents.

"In addition to the above reasons, the possession of a tent floor in a camp invariably adds to pride in appearance, and it is an indisputable fact that a soldier may not keep his clothing and equipment in even a reasonably correct condition if he is forced to be housed on bare soil."

21. FOOD, BY DEPARTMENTAL SURGEON OF SOUTHERN DEPARTMENT.

Kitchen and mess management has been under constant inspection and systematic supervision. Faults in sanitary arrangement were corrected as promptly as possible. While not included within the period covered by this report, it may be of interest to note that careful investigation of the physical condition and personal hygiene, including investigation to determine the presence of disease carriers, has been instituted for all cooks and others handling food. Food has been satisfactory in character and sufficient in amount; no complaints as to preparation are reported.

A vigorous campaign against flies has been kept up throughout the year. The short winter of these Southern States allows a long fly-breeding season and, in reality, flies are to be found on occasional warm days even in the coldest season of the year. Thorough screening of all kitchen and mess facilities has been maintained and active methods of extermination with traps, poison, and swatters have been early instituted.

22. WATER SUPPLY, BY DEPARTMENTAL SURGEONS.

A. SOUTHERN DEPARTMENT.

Notwithstanding the severe drought conditions which prevailed throughout this territory, water supply in general gave no great trouble and was sufficient. In no case was epidemic reported attributable to water supply.

At Leon Springs the shortage of water was most acutely felt for the Artillery troops and training camp located there. Special studies of the water situation at this point have been made the subject of a special report. The maximum available supply of 450,000 gallons per 24 hours is not sufficient for the almost 10,000 men at times located there with the accompanying animal equipment of artillery of Cavalry organizations.

B. FORT OGLETHORPE, GA.

Under the heading "Water," the surgeon in charge stated that "through the laboratory much of the early work of sanitation was accomplished. The water supply as delivered to the hospital was found to contain *B. coli.* The supply was investigated and found to be made up of two sources, one the City Water Co. of Chattanooga and the other deep wells on the post. The former supplies about 2,000,000 gallons, the latter 500,000 gallons per day. This is inadequate. Frequently the hospital is without water, which causes great inconvenience and results in insanitary conditions in the toilets, which become clogged, much to the discomfort of the patients. Personal inspection and laboratory studies showed the Chattanooga supply to be Tennessee River water, which is sedimented, sand-filtered, and chlorinated. This was found excellent. The post supply is made up of deep wells averaging 450 feet in depth, and all contain *B. coli.* Contaminated wells were closed where possible and placarded."

23. CLOTHING, BY DEPARTMENTAL SURGEONS.

A. EASTERN DEPARTMENT.

Fort Hamilton, N. Y.—The surgeon reports that the shoes of the men wore out before those sent in for repairs were returned, thus causing a constant lack of proper shoes and subsequent increase of sickness.

B. CENTRAL DEPARTMENT.

The inability to obtain winter clothing, especially the olive-drab woolen clothing, for men has contributed materially to respiratory afflictions. Requisitions have been promptly made and approved for clothing, but the greater part of the Tenth Infantry has not as yet been supplied with heavy clothing.

C. SOUTHERN DEPARTMENT.

Proper clothing was not especially lacking till late in the fall of 1917 and in the early months of 1918, when the winter developed into the most severe for cold weather on record. The lack of warm clothing then became acute and applies to not only woolen uniforms, breeches, and blouses, but also to overcoats and blankets, and it was not surprising that the men crowded together in badly ventilated rooms in order to keep warm when their outer clothing consisted of cotton khaki and their bedding of but two thin blankets.

24. HOSPITALS, BY DEPARTMENTAL SURGEONS.

A. SOUTHEASTERN DEPARTMENT.

Constant reminders were sent to the Surgeon General's Office that the necessary Medical Department construction was not being carried out in compliance with original orders on the subject. To partially offset this delay in preparation for reception of the sick, it was necessary to request the commanding generals of the Northeastern, Eastern and Central Departments to have field hospitals and ambulance companies precede the other troops, to immobilize as temporary hospitals until the delayed medical construction was completed. At the National Army cantonments, where no sanitary unit was scheduled to be assembled, a complete field hospital was shipped.

B. EASTERN DEPARTMENT.

Fort Jay, N. Y.—The surgeon reports that the old hospital building is in a dilapidated state, being an old frame building with unsanitary plumbing, and that it has outlived its usefulness as a hospital. A new heating plant has been installed in the cellar of the building.

Four new buildings, each containing 32 beds, have been almost completed in addition to a mess hall. Buildings are lighted by electricity.

The capacity of the prison ward is for 10 beds. On account of the crowded condition of this ward, it has often been necessary to put convicts in the same wards with enlisted patients, a procedure which is unjust to the latter but which, under the circumstances, could not be avoided.

Fort Hamilton, N. Y.—The surgeon reports that the new hospital building can not be used for hospital purposes because the steam-heating plant is not yet completed. The building is being temporarily heated by the Quartermaster Corps, and is at present being used to house some of the drafted men recently received at the post.

Fort Monroe, Va.—The surgeon, Fort Monroe, Va., reports that the hospital there has acted as a base hospital for the surrounding territory, receiving patients from Camp Stuart and Camp Hill at Newport News, Va., Langley Field, Hampton, Va., Richmond and Norfolk, Va., and quite a number from merchant ships, United States and foreign naval vessels, there being 150 patients in hospital at times. Two new wards are about completed, which will increase the hospital capacity to 220 beds without crowding. New buildings have been asked for to house the increased number of enlisted men, Medical Department, needed for the increased capacity of the hospital.

There are 8 female nurses, Army Nurse Corps, on duty at this post, and the surgeon expects that it will be necessary to increase this number to 14 within the next few months. The erection of a building to house the Army Nurse Corps has been requested.

25. MEASLES, BY DEPARTMENTAL SURGEONS.

A. CENTRAL DEPARTMENT.

There were several epidemics of measles, the larger number of cases being at Fort Riley, Kans., which had 247 cases. There were also 156 cases at Fort Benjamin Harrison, Ind., 121 cases at Fort Omaha, Nebr., 72 cases at Fort Leavenworth, Kans.; 37 cases at Fort Sheridan, Ill.; 35 cases at Fort Des Moines, Iowa; 34 cases at Fort Snelling, Minn.; 14 cases at Fort Wayne, Mich.; 10 cases at Fort Crook, Nebr.; and 3 cases at Fort Brady, Mich.

B. SOUTHERN DEPARTMENT.

These two diseases have continued to be very prevalent throughout the year. Many of the men claim to have had the diseases in childhood. Whether or not our future knowledge will show that different strains of the causative organisms of these diseases exist, as the several types of pneumonia, is of course only a matter of speculation at the present time; it might account for the absence of immunity in well authenticated cases of previous attack. As mentioned later, when discussing the presence of hookworm, another cause of the recurrent cases seems to be the lowering of physical standard by reason of the anemia incident to anchylostomiasis and malaria.

Complications of broncho-pneumonia were especially common following measles. In fact, probably the majority of these cases started in that manner. Not a few of the deaths reported as broncho-pneumonia undoubtedly were due primarily to measles.

26. VENEREAL DISEASES, BY DEPARTMENTAL SURGEONS.

A. CENTRAL DEPARTMENT.

Prophylaxis is promptly observed when required and all stations fully equipped and intelligent enlisted men designated for instruction and record keepers. Much of the success of prevention of venereal diseases is the result of proper "plain talks upon venereal diseases" by medical officers detailed for this purpose. At one time a lecture was given to the Tenth Infantry, the regiment being divided into battalions. Instruction was given to the men upon the dangers of gonorrhea, syphilis, etc., calling attention to the prophylaxis required, the personal danger of contamination, and its results. Attention was especially directed to Army Regulations, and to the Manual for the Medical Department in relation to immoral conduct. The efficient and hearty cooperation of the post commander with city authorities in controlling the vice conditions in the city of Indianapolis and its environment has mitigated in a large measure the spread of venereal diseases.

Venereal diseases figure conspicuously among the causes of admittance to the hospital, but have by no means advanced in volume in proportion to the increase of size of command. Adequate provisions for prophylactic treatment was provided at the beginning of the influx of troops, and the number of treatments taken indicate that a very negligible percentage of the admissions for venereal diseases had failed to avail themselves of prophylactic treatment.

Fort Riley, Kans.—On account of the great influx of new troops in newly formed organizations, it was difficult to carry out such prophylaxis in detail at various times. The number of venereal diseases, however, has been a good deal below normal.

Fort Robinson, Nebr.—A conspicuously small number of venereal cases originated at this post, one syphilis and four gonorrhea. The system of inspection has been efficient in reducing the cases to a minimum.

B. SOUTHERN DEPARTMENT.

Grouping the three venereal diseases together, syphilis, chancroid, and gonorrhea, the Regular Army shows 5,394 cases, or 94 per 1,000, while the militia shows 1,048 cases, or 58 per 1,000, a higher ratio for the militia than a year ago but still markedly below the rate for the Regular Army. That figure, however, shows an improvement over a year ago when the rate was 140 per 1,000. It is believed that many cases of venereal disease are unreported in militia organizations.

27. MALARIA, SOUTHERN DEPARTMENT.

The incidence of malaria shows a decided decrease over the figures of a year ago. The combined rate for Regulars and Militia is 6.8 per 1,000, or exactly 10 less per 1,000 than for the year 1916.

28. PHILIPPINE DEPARTMENT, MANILA, P. I.

(Extracts from department surgeon report.)

The general condition of this department is that of peace, and as a matter of fact it is more peaceful than it ever has been before since American troops were sent to these islands.

Four stations have been abandoned during the year: Regan Barracks, Warwick Barracks, Fort San Pedro, and Ludlow Barracks.

The troops were stationed at 13 posts and one subpost. No new posts were established. Three more posts are scheduled to be abandoned early in 1918.

The food and clothing provided for the troops has been excellent. The water supply generally, although somewhat expensive as far as that for drinking and cooking is concerned, has been excellent in quality and abundant. Distilled water has been furnished for drinking and cooking purposes at many of the stations; others are supplied with artesian water which is of an excellent quality.

A. HOSPITALS.

The department hospital is in a very good state of repair at the present time. It has been repainted during the past year and an excellent X-ray clinic has been provided.

There were 1,807 cases transferred to the department hospital for treatment, namely 1,698 American white, 71 American colored, and 38 Philippine Scouts. An average of 109 patients was in hospital during the year, of which enlisted men and officers were 63 and civilians 46.

The hospital at Fort Mills is a large concrete building, sufficient in size to provide for all the demands made upon it, with the exception of quarters for the enlisted personnel.

The hospital at Fort McKinley is a large concrete structure, which is much larger than is needed for the present garrisons, there generally being about 140 or 150 vacant beds.

The hospital at Camp Stotsenburg, which was an old dilapidated wooden structure, has been rebuilt, and while not as large or of as good construction as is desirable for this station, yet it was the best that could be done under the present restrictions, which do not permit of permanent construction at this station.

The hospital at Camp John Hay, which is at Baguio, in the mountains, is an attractive building, and is used to a limited extent as a convalescent hospital for cases arising in other posts of the department.

B. DENTAL SANITATION.

Considerable attention has been given to the work of the dental surgeons. In this connection the condition of the teeth of enlisted men is looked upon as an unsanitary condition that should be corrected if possible with the limited means at hand. As an unsanitary condition it becomes a matter of personal concern of each post surgeon. The dental clinic is considered to be a department of the hospital the same as the eye or ear department, or the laboratory. The initiative in directing the work of improving the unsanitary condition belongs to the surgeon the same as in any other unsanitary condition, instead of the initiative being taken by the patient as contemplated by Army Regulations. It needs the teamwork of the organization commanding officers, the surgeon, and the dentist to be most effective. The treatment of the unsanitary dental conditions of the enlisted men has the first call for consideration. At the same time the facilities of the dental clinic are apportioned between the needs of officers, their families, and emergency dentistry, and the correction of the unsanitary condition of the soldiers' teeth.

The necessity for system in this matter is shown by a survey of a detachment of the Medical Department of 90, which showed that 70 per cent needed some dental treatment, extending from filling 1 or 2 cavities in one, to the extraction of 17 teeth in another. A survey of one company of Engineers showed that there were 525 cavities. It is believed that about 70 per cent of the enlisted men of the line need some dental treatment.

C. HOUSING OF THE TROOPS.

The troops in this department are, as a general rule, well housed except as to the China expedition. At present there exists there a serious overcrowding. The troops are quartered in rented buildings owned by a Chinese corporation which in constructing the new buildings made no provision for ventilation and has thus far refused to provide any. The crowded condition at present allows less than 500 cubic feet in the dormitories, and at times about 300 feet to the prisoners in the guardhouse. This close confinement shows itself in the high rate for tuberculosis and pulmonary disease. Recommendation has been made to reduce the forces so as to allow 700 cubic feet per man, or secure other quarters. This matter is still under consideration.

The screening of the barracks at Camp Stotsenburg has been completed during the past year. This screening was first recommended 12 years ago.

D. HEALTH OF THE TROOPS.

The increase in both the admission rate and constantly noneffective was due to alcoholism, dengue, and venereal diseases; the admission rate for disentery was reduced from 8.8 in 1916 to 5.0, malaria from 54.8 to 51.7, and tuberculosis from 5.0 to 4.9 per 1,000.

As compared with 1916 alcoholism shows an increase among white and colored Americans, and a decrease among Philippine scouts; dengue and venereal diseases a general increase all around; dysentery a general decrease; malaria a decrease in American white, the increase being in American colored and Philippine scouts, while tuberculosis has decreased in American white and Philippine scouts and increased among American colored.

The comparative admission rates for the posts in the Department for the years 1916 and 1917 are given below:

TABLE No. 149.—*Admission rates, posts, Philippine Islands (absolute numbers).*

Posts.	Admission rates per 1,000.	
	1916	1917
Augur Barracks	673	737
Camp Eldridge	1,175	1,219
Camp John Hay	666	629
Camp Keithley	432	586
Camp McGrath	758	522
Camp Overton	517	637
Camp Stotsenburg	1,203	1,217
China expedition	979	939
Cuartel de Espana	885	1,446
Fort Santiago	494	615
Fort Mills	604	648
Fort McKinley	915	922
Pettit Barracks	316	529

Malaria.—The malarial situation continues to show great improvement, the admission rate being 51.7 per 1,000 against 54.8 per 1,000 in 1916; 65.6 in 1915, 93.9 in 1914, 125.4 in 1913, and 188 in 1912. The rate per 1,000 in 1917 was the lowest since American occupation.

TABLE No. 150.—*Admission rates per 1,000, posts, Philippine Islands.*

Posts.	Admission rates per 1,000.	
	1916	1917
Camp Stotsenburg	186.9	143.9
Fort Mills	61.3	49.8
Pettit Barracks	40.2	190.3
Augur Barracks	96.3	74.6
Camp Keithley	12.8	17.2
Camp Eldridge	27.3	42.9
China expedition	9.6	2.9
Fort Wm. McKinley	29.9	23.2
Camp John Hay	14.2	1.8
Camp McGrath	15.8	53.4
Cuartel de Espana	8.9	1.6

The increase at Pettit Barracks was largely due to disease being epidemic at that station during the month of May, in which there were 49 cases admitted (total cases for the year, 87).

Dengue.—The admission rate for this disease was 55.6 against 11.3 per 1,000 in 1916. The increase was largely due to dengue being prevalent during May, June, and July at Cuartel de Espana and at Augur Barracks during April, May, and June.

Dysentery—amoebic and bacillary.—Thet otal admissions in the department for 1917 were 93 as against 170 in 1916, a decrease of 77 cases, or 5 per 1,000, as against 8.8 in 1916.

Most of the cases of dysentary were probably due to contact with natives who had this disease. A muchacho at Camp Stotsenburg, working for bachelor officers, infected several of them.

Smallpox.—Seven cases of smallpox occurred, one among Americans and six among Philippine scouts; all recovered. Cases occurred at the following stations: Augur Barracks, 1 scout in January; Camp McGrath, 1 scout in February, and 2 scouts in December; China, 1 American in May; Warwick Barracks, 2 scouts in November.

Typhoid fever.—No case reported during the year.

Leprosy.—Two cases were discovered among the Philippine scouts, one at Augur Barracks and one at Ludlow Barracks. Both were discharged on certificate of disability and turned over to the civil authorities.

Beriberi.—There were two cases of beriberi at Augur Barracks in August. Both were Philippine scouts.

Cholera.—No case reported during the year.

Fort Mills.—Although the admission rate and constantly noneffective rate are somewhat higher than for last year, due principally to venereal diseases and dengue, the admission rate per 1,000 is the lowest in the department for American troops.

No diseases of sufficiently marked prevalence to be deemed worthy of note have occurred during the year among the command. During the last two months of 1917 there were a somewhat large number of cases of mumps and chickenpox, and several of whooping cough. At the stockade for Bilibid prisoners, which, although it has served for several years, is unsatisfactory in almost every particular, and to which it is understood, extensive alterations and repairs are contemplated, a large number of cases of ophthalmia have occurred.

Venereal diseases.—There has been a slight increase in the venereal diseases during the past year. This is largely due to the large number of new recruits received in this department, and also to the constant change of officers with organizations, these officers being as a rule with less experience than those who formerly served with the commands, and lastly to the increase in pay which the soldiers have received during the past year. All methods for the prevention of venereal disease, providing abundant places for taking prophylaxis; trials of patients for failure to take prophylaxis; lectures, circulation of instructions in regard to venereal diseases have been used in an effort to keep down the rates of venereal diseases.

The records of the Department Judge Advocate's office show that for little less than five months there were 268 trials for failure to take the prophylaxis, in comparison with 1,094 trials for failure to take the prophylaxis in the whole Army during the year ending June 30, 1916.

E. CHINA EXPEDITION, TIENTSIN, CHINA.

The admission rate and constantly noneffective rate per 1,000 are considerably lower than for the previous year. The admission rate for venereal disease also shows an improvement, being 355.6 per 1,000 against 378.6 for 1916.

The present sanitary condition of the post as a whole is good but consider the various company barracks entirely too small to allow the required amount of floor space per man. The average amount of air space per man in the various barracks is about 400 cubic feet. The barracks were very poorly heated with stoves, and as the weather was a bit cold the men would not open the windows. As a result the squad rooms have been very poorly ventilated, especially at night time. In a recent inspection made by me during the night I found men sleeping in six company barracks without a window open. On this same inspection I found 30 prisoners sleeping in two small roms having an aggregate air space of less than 4,500 cubic feet; one room had no windows open while the other had one small window of about four square feet open. The hospital building is also too small. It seems that the plans called for a 30-bed hospital, allowing each patient about 1,000 cubic feet of air space. However, it has been necessary to increase the number of beds to 60, and the hospital averages between 50 and 60 patients at all times. I consider the crowded condition and poor ventilation of the barracks as one of the principal factors for giving this hospital its high rate of admission.

29. PANAMA CANAL DEPARTMENT, ANCON, CANAL ZONE.

(Extracts from report of department surgeon.)

The Panama Canal Department became a separate department on July 1, 1917, in compliance with General Order 76, War Department, paragraph 6, June 26, 1917. Previous to this time it had been a part of the Eastern Department, the great advantage of having it a separate department is that much time is saved by having action taken in matters which before this had to go to Governors' Island for action. War conditions, especially the shortage of medical officers and more particularly of the Regular Medical Corps, have caused the department surgeon to assume the duties usually carried out by a sanitary inspector and a disbursing officer.

This department includes the following posts: Forts Sherman, Randolph, and De Lesseps, Artillery posts at the Atlantic end of the Canal; camps at Gatun, Gaillard, Empire, and Otis; Infantry posts and at Corozal, a mixed mounted post, consisting of Cavalry, Field Artillery, Engineers, Signal Corps, and Ambulance Company No. 8; Fort Amador (formerly Grant), a Coast Artillery post guarding the Pacific terminal of the canal, and Quarry Heights garrison, the department headquarters post and station of the provost guard. In addition to these main stations are a number of substations both Artillery and Infantry guarding the coast line, locks, docks, etc., owing to existing war conditions. Also a number of mapping parties are out in the jungle making maps, surveys, etc., for the Engineers. These men become exposed to mosquitoes and this exposure has a tendency to increase the malaria.

The general health of the command has been very good. There were no epidemics or other unusual incidence of infectious diseases, except an epidemic of measles and

German measles which was imported from Porto Rico by that regiment on its arrival from Porto Rico and which continued until nearly all nonimmunes of the regiment had taken it. No deaths occurred and it has subsided now.

A. MALARIAL FEVER.

This disease, though present to a moderate degree owing to so much outside work as before mentioned has not been bad and is readily kept under control.

All barracks and quarters are wire screened and very few if any mosquitoes are found at any of the posts, some of them being absolutely free.

Many of the cases of malaria are recurrent and occur in men who have contracted the disease while in some of the outlying jungle stations and have recurrences at intervals afterwards.

There have been seven cases of this disease and, as in other tropical countries, it progresses very rapidly after being once contracted. All men who are found to have it are promptly transferred to Fort Bayard, N. Mex., except the Porto Ricans who are discharged and returned home.

It is believed that inferior scrutiny by the examining surgeons at time of enlistment is more to blame for the increase in this disease than the environment of the tropics.

Care of sick. —The care of sick in this department is done by sending all serious cases or those likely to be sick for more than a few days to Ancon Hospital, a large well equipped hospital at Ancon the southern terminus of the canal. This hospital is under the management of the Panama Canal and the Army patients admitted therein are on the same basis as if admitted to civilian hospital and the Army Medical Department pays $1.10 per day for each case with additional charges for any form of operation, X-ray or special treatment and the Quartermaster Department of the Army pay 40 cents per day for subsistence.

A few beds, about a dozen, are kept at the various posts for the accommodation of the mild cases but the buildings furnished are in most cases crowded and poorly fitted for hospital purposes. Some cases from the adjacent posts are admitted to Colon Hospital at the other end of the Canal and are treated there on the same terms as at Ancon.

It is recommended that all Army cases sent to these hospitals be treated and attended only by Army Medical Officers as this would be more satisfactory to the patients themselves, would shorten the loss of time in hospital, would have the Army nomenclature for diseases and would give the medical officers a better opportunity to see and attend the cases cropping up among soldiers, officers and their families.

B. SANITATION.

This subject has taken up most of the time in order to continue and keep up the good work which was so well done when the canal was built. A civilian sanitary inspector is employed by the month, whose duty it is to have charge of the sanitary gangs in the different posts and lay out and supervise their work and to find out and investigate sanitary defects on all the military reservations. The present incumbent, is a most careful and conscientious man and performs his varied duties in an excellent manner. He is thoroughly familiar with mosquito control. The mosquito with its partner, malaria, is the chief enemy of our sanitary work and to rid the posts and their surroundings of it is our principal aim. For this purpose, sanitary gangs (negroes) are employed in each post and paid from funds allowed from medical and hospital appropriation by the Surgeon General, $50,000 being allotted to this department for this purpose. Out of this fund are purchased oil, larvicide, implements for cutting grass and undergrowth, tiling, cement and materials for ditching. Moreover, motor ambulance supplies, ice, and laundry are paid from this account, but the largest item of all is the pay of these sanitary gangs who do the work. Nearly all posts are now practically free of mosquitoes and the rest are nearly so, and malaria is not contracted in the posts but on outside duty, in the jungles, on the locks and at other similar substations. The posts in the jungle are now being cleared and ditched and it is hoped will soon be free or almost so of malaria. Our principal work is on these places now.

The screening of all occupied buildings is good but it is necessary to repair or replace it frequently owing to dampness of the climate and the frequent breaks which occur in it.

A great deal of tile draining has been done and some concrete draining also and the results achieved are excellent; swampy wet ground has been made dry.

Nearly all the buildings at all the posts except the new ones are old, fast decaying, overcrowded and, worst of all, full of vermin. Many of these buildings have been used by the canal employees and others, among whom were negroes. Thus the presence of bedbugs is readily accounted for. They make many of the buildings intolerable. All efforts to get rid of the bugs permanently are futile, because many manage to escape destruction in the cracks of the old buildings and soon reappear in increased numbers. The best and only solution of this problem seems to be the construction of new posts of concrete whose buildings will not offer vermin shelter and protection.

The overcrowding in some posts is very bad particularly Camp Otis, where the Porto Rican regiment is stationed; but other Infantry posts are almost as bad. They were evidently planned on the basis of the old peace strength of companies, and when the companies were increased to war strength the same buildings were used; which has caused overcrowding. New barracks and extensions are being built at some posts now, but this is only temporary relief. There is plenty of good shower baths for the men; which is not only a comfort for them but an excellent sanitary measure.

30. HAWAIIAN DEPARTMENT, HONOLULU, H. T.

(Extracts from reports of department surgeon.)

A. GENERAL.

Comparison with former years.—The year 1917 has the highest morbidity rate of any since the formation of the Hawaiian Department. This high rate of admissions and days lost in line of duty is to a great extent due to the infectious diseases of childhood introduced by recruits, and also to the fact that young untrained men, until seasoned, are more liable to appear on sick report. Many injuries incident to intensive training added not a small proportion to this increase. Diseases not in line of duty, especially venereal, show a gratifying decrease.

Epidemic diseases.—With the arrival of numerous recruits, especially in the middle half of the year, there were introduced into the department measles, mumps, spinal meningitis, scarlet fever, and other infectious diseases. In all cases the recently joined men were kept separate until after the period of incubation had safely passed, but in spite of best efforts some infection occurred in the command.

Typhoid fever.—There were 4 deaths among 55 cases of officers and enlisted men (practically all immunized). Among the civilians at Castner, approximately 1,100, there were 48 cases of typhoid due to the water-borne epidemic. Thirty-three of these were treated under Army supervision at Schofield Barracks and department hospital with 4 deaths; fifteen were treated under civilian auspices with 3 deaths. Of the 8 cases of contact infection there was 1 death. The full history of the water-borne epidemic at Schofield Barracks (55 cases, officers and enlisted men; 48 civilians) will be found in completed reports of board of medical officers at Schofield Barracks.

Venereal diseases.—Taking the department as a whole, the rate per 1,000 of Hawaiian infection (38) is most creditable when compared with that of 1916 (76.5), or 1915 (67.5). Comparing the rate per 1,000 of the first (10.7) and second (11.6) quarters with the third (8.3) and fourth (8) quarters, a decided decrease is noted. As the total number of prophylactic treatments per 1,000 of mean strength in the first quarter of 1917 was 408, in the second 439, in the third 506, and in the fourth 495, the above noted decrease in venereal disease would not appear to be due to a greater continence, but can be attributed to the fact that the more or less absence of alcohol in the last two quarters had much to do with the early and proper use of the prophylactic treatment after exposure, and thus prevented infection.

Transfer of patients to United States.—There were 253 patients transferred to the Letterman General Hospital during the year. Of this number 73 were for tuberculosis, 70 for mental and nervous disorders, 16 for syphilis, 14 for results of injuries, and 80 for various other conditions. This is an increase of 99 over last year, and is due to a greater average strength and a weeding out of many unsuitable recruits.

B. SANITATION OF POSTS.

De Russy.—A considerable tract of land on the western side of the reservation, which is low, with water standing on it, being at the level of the water in the bay, affords an excellent breeding place for mosquitoes. An estimate submitted to Congress by the Engineer Department for completing the filling in of this low land was disallowed as not being a proper charge against the Engineer Department.

A portion of this low land (holes and swamps), in rear of the new quartermaster stables, is being filled in by post labor as available from day to day. The balance is being oiled to control mosquitoes propagation, but is not entirely successful, as some mosquitoes still breed on privately owned swamp land adjoining the reservation.

Kamehameha.—In this sanitary report for March, 1917, the surgeon reports a photograph forwarded to the Adjutant General, showing conditions at the post during a recent flood, but with no recommendations. In his indorsement on this report the department commander invites the attention of The Adjutant General to recommendations contained in the February report, and states: "This matter is now in the hands of the constructing quartermaster, who is preparing plans and specifications for the flood gates as recommended by the district engineer, United States Geological Survey." Nothing further appears to have been done in the matter.

Ruger.—Insufficient outlet for sewage and drainage from the post laundry and toilets on the battery side of the fort during heavy rains is noted in the December sanitary report. The commanding officer, coast defenses of Oahu, states in his indorsement thereon of January 3, 1918, that the special sanitary report referred to therein will be forwarded in the near future recommending remedial action. The special sanitary report mentioned has not as yet been received in this office.

Schofield.—The sewer system for the post has been installed with the exception of the oriental section and is satisfactory. The oriental section for laborers of the Quartermaster Department, while much improved, is still far from sanitary. It can only be remedied by a complete reconstruction on sanitary lines on ground sufficiently high to admit its connection with the sewer system of the post.

The water supply has been the subject of much controversy since the outbreak of typhoid fever at the end of September and beginning of October. A board of officers (2 Engineer and 1 Quartermaster) are engaged in further study and elaboration. Meanwhile temporary chlorination plants are installed. This matter is fully discussed in the various reports of the typhoid epidemic.

Shafter.—The sewer system has been reported inadequate. Action is awaiting final determination of the ultimate size of the garrison.

A steam laundry has been recommended as a sanitary measure, but the same is held up owing to unsettled conditions. New arrangements for the operation of the post laundry were made in September which eliminated many of the faults complained of.

An enlarged dispensary has been frequently urged and is a necessity.

Personnel.—But six officers of the Medical Corps remained in these islands December 31, 1917. (Two of these were ordered to the States by cablegram January 19.)

Many of the reliable noncommissioned officers were promoted to line or staff commissioned ranks and others sent to the mainland, where their services are more urgently required. The replacing of these by only partially trained men (in a military sense) has affected efficiency and is one of the natural results of unpreparedness for war. The troops of these islands have been to a great extent under conditions existing prior to war and as such can well accommodate themselves to the altered conditions of a new personnel.

Instruction to recently joined officers of the Medical Reserve Corps has been given at both the department hospital and Schofield Barracks. The results have been good, though one can not expect independently acting professional men of middle life to readily grasp Army methods so different from those to which they have been accustomed.

III. Hospital Division.

1. HOSPITALIZATION PROGRAM.

Soon after the United States entered the war the need of a definite hospitalization program of larger scope was apparent. Early in July, 1917, a hospital division was created in the office of the Surgeon General, which was charged with the responsibility of providing hospitals in the United States for the cantonments of the National Army and the National Guard encampments, and general hospitals and special hospitals for the receipt of sick and wounded from overseas and patients transferred from the various camps, who required prolonged treatment. In other words, this division was charged with the responsibility of handling the entire program of hospitalization in the United States and, in addition to this, with the task of organizing all overseas units, such as base hospitals, evacuation hospitals, ambulance companies, field hospitals, hospital trains, and hospital ships.

Early in 1918, as the work of the department was increasing enormously, it was deemed advisable to effect a reorganization for the purpose of better control and more efficient service resulting from better distribution of responsibility.

Inasmuch as the first divisions of the new National Army were to be ordered to camp in the early fall, it was necessary to proceed rapidly with the development of preparations for the establishment of large hospitals in all of the National Army and National Guard camps. Plans were developed, hospitals constructed, personnel selected, and with the opening of the camps, 32 hospitals, with a normal bed capacity of 44,000, were put in operation early in the autumn of 1917, in time to receive the sick from these large camps. Twenty-five of these were hospitals of 1,000 beds or over. It will therefore be apparent that the accomplishment of this task represented no small achievement.

At the same time plans have proceeded for the preparation of hospitals for the sick and wounded overseas. In general the basis of the hospitalization program is as follows:

A. FOR THE CARE OF THE SICK AND WOUNDED IN THE UNITED STATES.

Hospitals designed to take care of approximately 4½ per cent of the command have been constructed in the National Army cantonments and National Guard camps.

Hospitals at posts and general hospitals have been enlarged by the construction of temporary wards near the main buildings. The barracks of a few posts have been obtained and others have been requested. Embarkation and debarkation hospitals have been provided and others are to be provided at the ports by construction of new temporary buildings and the use of hotels and other buildings suitable for the purpose.

From time to time it has been necessary to add additional buildings to the base hospitals in the National Army and National Guard camps. In general this extension has been accomplished by the addition of 12 two-story convalescent barracks for walking cases, leaving the one-story buildings for the more seriously ill, and affording better means for the segregation of cases.

B. FOR THE CARE OF THE SICK AND WOUNDED FROM ABROAD.

A survey of the civil hospitals of the country was made early in the summer, and although of a superficial nature it disclosed the fact that it would not be practicable to rely to any great extent upon the civil hospitals of the country for the care of sick and wounded soldiers; first, because it was apparent that the civil hospitals would be called upon to meet an ever-increasing demand from the civil population; second, because to use the civil hospitals to any great extent would mean the distribution of soldiers in such small groups that it would make it exceedingly difficult to keep military control over them or to institute and carry out any constructive program for rehabilitation and reeducation.

A study has been made of available sites for hospital purposes, of large buildings, such as hotels, factories, etc., which could be used as hospitals, and of smaller places suitable for convalescent camps and homes. The resources of the Public Health quarantine stations and insane asylums of the country have also been made of record.

That part of the hospitalization program dealing with the care of sick and wounded from abroad has been based upon the figures from England and Canada, from which the conclusion has been drawn that it will be necessary to provide in the United States a bed capacity of

3½ per cent of the total number of troops serving abroad, the number of beds gradually increasing, from the fact that many cases will require prolonged treatment. In general it is planned to provide adequately in the nature of clearing hospitals or debarkation hospitals at the ports, in order that a sufficient number of beds may be available to receive any number of troops which may be returned. It is planned to provide an organization at each of these clearing hospitals which will make possible the speedy assignment of these patients to hospitals in the interior, distributing them in accordance with the nature of the disease or injury, so far as possible returning them to the section of the country from which they came. It is planned to place in each National Army district a large hospital group, sufficient to care for the men of that district returned from abroad, these hospitals to be conveniently located as to railroad facilities, the professional facilities of the large medical centers, and with due regard to the desirability of contact with industrial activities. It is intended to make these hospitals complete general hospitals, capable of providing for the physical and general reconstruction of all patients requiring such treatment. For this purpose use is being made of military posts, which may be converted into hospitals and of hotels and other suitable buildings which may be leased and made available for hospital purposes.

This program is proceeding fairly satisfactorily, although much delay has been incurred due to the fact that many of the military posts which have been requested for assignment to the Medical Department have not been made available. However, it is expected that hospitals in sufficient number and with adequate capacity will be provided at all times for the reception of the returned sick and wounded.

In the early stages of organization, officers of the regular Medical Corps were detailed from among the junior majors to organize, equip, and administer the military hospitals, the balance of the personnel being selected from the Medical Reserve, Sanitary, and Army Nurse Corps, enlisted men of the regular Medical Department, and by transfers from the draft and training camps. Officers for the administrative positions were found with great difficulty and, in most instances, were supplied from the Sanitary Corps by commissions given the more experienced noncommissioned officers of the Medical Department. These officers have performed most valuable service in the positions of adjutant, registrar, mess officer, and medical supply officer. The chiefs of the medical, surgical, and laboratory services have been selected from the best known and most capable and distinguished men of the profession in civil life, and have, with very few exceptions, contributed greatly to the success of these hospitals. The senior assistants on these services have also been specially selected, either by reputation or after observation at hospitals or training camps has proven their worth.

Women nurses have been supplied to all of these hospitals as rapidly as accommodations for them became available. Full assignement of nurses to duty at all hospitals would have been made in October, had quarters been available, but it was several months after the camps were built before nurses' quarters were completed, which made it impossible to assign these graduate nurses who were so badly needed. All the camps are now provided, however, with a competent and adequate supply of nurses. In general, the effort is made to assign nurses in the proportion of 1 to every 10 patients.

The original supply of enlisted men was obtained from the Medical Department and consisted of a detachment of 120 men for National Army cantonments and 100 men for the National Guard Camps. This detachment was increased by additions from the draft, up to 300 men for 500-bed hospitals, 360 for 800-bed hospitals, and 400 for 1,000-bed hospitals. In many instances it has been impossible to attain these figures, due to the inability to obtain men from the draft. At some hospitals enlistments have been made which have brought the detachments up to the figures given. In the last few months men have been assigned up to the quota. The majority of these enlisted men are absolutely untrained for their duties, and at first there was much embarrassment and inefficiency because of this lack of training. Courses of instruction have been going on at all hospitals and the reports indicate that these men are developing into very satisfactory hospital attendants. An effort has been made wherever possible to transfer men with special qualifications for duty in the office and in other positions requiring special training, such as stenographers, typists, cooks, machinists, accountants, etc.

Owing to the anomalous position occupied by these base hospitals at the cantonments, great difficulty was experienced in determining the exact relation of the hospital to the division and to the Surgeon General's office. Existing regulations were modified and a working plan adopted. A new set of regulations was authorized by the Adjutant General on October 22 and has been found to operate satisfactorily.

Regulations governing the internal administration of these hospitals have been those prescribed in the Manual of the Medical Department for General Hospitals. Specific hospital orders for the administration of cantonment base hospitals were very well covered in regulations drawn for the base hospital at Fort Bliss, Tex., and were based upon the experience of some 16 months in the handling of similar situations. These regulations were sent to each base hospital for the information and assistance they might afford to the commanding officer.

The arrangement of service prescribed in the Manual of the Medical Department was modified by memorandum approved by the Surgeon General and the Secretary of War as follows:

Attention is called to the fact that the memorandum previously issued by the Surgeon General (recognition of sections representing specialists) and paragraph 290 is amended to provide for three services, namely, surgical, medical, and laboratory, with a chief for each service, and further, to provide that each of these services shall include the following special sections, or as many as may be necessary (500-bed basis):

SURGICAL SERVICE.

One chief of service; general, chest: 4 surgeons—abdomen, fractures; 4 surgeons (head section)—brain, eye, ear, nose, and throat, plastic (face and mouth); 1 surgeon, orthopedic; 1 surgeon, urology; 1 roentgenologist; 2 dentists.

MEDICAL SERVICE.

One chief of service, 4 physicians (including 1 neurologist), 1 or 2 psychiatrists (in camp hospitals in United States).

LABORATORY SERVICE.

Includes pathology, bacteriology, serology, chemistry, morgue and public health laboratory work for the command. One chief of service (to cover pathology, bacteriology, and serology), 1 assistant. (All other laboratory workers are under the chief of this service).

For the head section a section chief may be designated, if desired.

The commanding officer will organize a convalescent camp as the conditions warrant.

The nursing service remains as at present, with the provision that the number of nurses may vary according to the needs of the service.

Paragraph 307 is amended to include the laboratory chiefs.

Attention is called to the fact that the provision of the several specialists in the medical and surgical organization is solely for the purpose of providing competent professional attention for the sick and wounded. The individual members of the staff, although assigned to duty with the organization for the purpose of providing special skilled service as the occasion may warrant, are nevertheless to be used as the chiefs of service and the commanding officer may direct. This provision is made in order that the work may be properly covered at all times and in order to accomplish the results expected of good organization and administration.

An adequate reference library has been provided in each hospital.

In October duplicate personnel was sent to each hospital at the National Army camps for the purpose of training officers and enlisted men and to supply sufficient personnel for the organization of base hospitals for overseas service. Special instructions were given that all of the important administrative and professional officers of the hospital should have understudies particularly adapted for the work. This was done for the purpose of providing competent men to serve as commanding officers, adjutants, registrars, mess officers, supply officers, or quartermasters, as the case might be, in order that a sufficient supply of men, trained in these duties, might be available for the staffing of additional general hospitals in this country and for the overseas base hospitals. One of the great difficulties has been the lack of trained administrative and executive officers. The plan has worked fairly well, although there has never been a time when it could be said that a reserve supply of well-trained administrative officers was on hand. During the last few months, through the cooperation of the food division, an effort has been made, and successfully, to obtain competent mess officers by selecting experienced caterers, hotel and club stewards and having them commissioned in the Sanitary Corps. In this way practically all hospitals of large size have been furnished with an officer, well qualified by experience, to serve as mess officer.

One of the most troublesome problems in the administration of the military hospitals is the management of the disposition of substandard medical officers. Instructions have been issued at various times that all substandard officers were to be given a thorough trial in the various branches of hospital work in order to find the work for which they were best suited, and if, after proper trial and instruction, it is determined that they are not capable of performing the duties of medical officers, they are ordered before efficiency boards for recommendation as to their discharge or other disposition.

The hospital division has been divided, as mentioned above, into four sections as follows: Bureau of administration, overseas section, section of selection, construction and repairs, and the Army school of nursing. An outline of the work of each section follows:

2. BUREAU OF ADMINISTRATION.

It has been the policy of the hospital division to interfere as little as possible with the details of internal administration of the various military hospitals, it being recognized that these hospitals can not be administered in detail from a central office in Washington. Efficiency boards have been appointed in each of the hospitals, consisting of the commanding officer and the chiefs of the medical, surgical, and laboratory services. These boards meet twice a month to conside questions of policy and needs of the hospital, and make a stenographic report of the meeting, with such recommendations as are deemed advisable. These reports are received in the hospital division of the Surgeon General's Office, as are also reports of the inspections of the sanitary and inspection divisions. Two inspecting nurses are serving in the hospital division, and from time to time they visit the various military hospitals, carefully inspecting the character of the nursing service. All of these reports are carefully scrutinized by a follow-up officer of the hospital division, and from time to time instructions are issued to the various hospitals indicating lines in which experience has seemed to demonstrate that administration can be improved.

A daily report of the bed capacity of all the larger military hospitals of the United States is received, giving the number of patients and the number of beds vacant. This work is in charge of one officer, who keeps the census report up to date and handles the transfer of all patients from one district to another and from the ports of debarkation to the general hospitals of the interior. This system is working very smoothly and with entire satisfaction.

The bureau of administration of the hospital division handles all questions of policy, sends out instructions from time to time, receives and checks reports from all efficiency boards, follows up all the delayed actions, handles all complaints, assigns and transfers all personnel, carries the census on daily reports, and tends to the transfer of all patients.

At the close of the fiscal year, June 30, the following hospitals are in existence and are handled by the hospital division, not including the many small post and camp hospitals more directly under the different territorial departments. (These hospitals during the year have treated 646,227 patients.)

3. ARMY SCHOOL OF NURSING.

It became apparent that if we were to keep up with the allowance of our tables of organization, some method would have to be found of supplementing the supply of graduate nurses by the use of unskilled women. After careful consideration of various plans, it was decided to establish the Army School of Nursing, with branch schools in various military hospitals in such number as might be necessary. This plan was approved by the Secretary of War May 25, and the first publicity was given out about June 21.

The plan provides a constructive method of increasing the supply of nurses for military service by the same system which has been found most successful in all of the civil hospitals of the country—the use of student nurses. Furthermore, the Army school plan provides the opportunity which the women of the country so earnestly seek—the opportunity of rendering service of a distinctive nature and, particularly, service in the care of the sick and wounded. This plan furnishes these women the opportunity desired, but prescribes that they must do the work under the regulations and the system prescribed by the Surgeon General.

During the month of June, 1918, the preliminary organization of the central office has been effected, printed forms have been adopted, and at the same time over 6,000 letters of application for papers or details of information have been received and disposed of. On June 30, 1918, 400 completed application papers have been filed. It is planned to start the first few schools during the month of July at the following hospitals: Walter Reed General Hospital, and the base hospitals at Camps Devens, Meade, Wadsworth, and Sherman. It is expected that during the coming year schools may be developed if the needs warrant it, and if the plan is found to be entirely successful, which may enroll as many as 10,000 pupil nurses.

It is confidently expected that the Army School of Nursing will prove the means of supplying to a large extent the necessary nursing service to the military hospitals of this country, thereby releasing the graduate nurses for the more important and strenuous work abroad, although other and additional measures are under consideration.

4. OVERSEAS SECTION.

1. The work of this section has been divided into two main parts:
   (1) Priority schedule.
   (2) Organization of units.
2. The units organized in this section are:
   (*a*) Base hospitals.
   (*b*) Evacuation hospitals.
   (*c*) Divisional sanitary trains.
   (*d*) Hospital trains.
   (*e*) Convalescent camps.
   (*f*) Convalescent depots.
   (*g*) Evacuation ambulance companies.
   (*h*) Army sanitary trains.
   (*i*) Sanitary squads.
   (*j*) Ambulance companies for camp use.
   (*k*) Hospital units.
   (*l*) Hospital ships.

3. One hundred and thirty-eight base hospitals were authorized by indorsement, Adjutant General's Office, December 28, 1917. Base hospitals Nos. 1 to 50, both inclusive, being Red Cross units, the preliminary organization and equipment having been handled by the American Red Cross under authority of the Secretary of War, the preliminary mobilization being as follows:

No. 1. Bellevue Hospital, New York City.
No. 2. Presbyterian Hospital, New York City.
No. 3. Mount Sinai Hospital, New York City.
No. 4. Lakeside Hospital, Cleveland, Ohio.
No. 5. Harvard University, Boston, Mass.
No. 6. Massachusetts General Hospital, Boston, Mass.
No. 7. Boston City Hospital, Boston, Mass.
No. 8. New York Hospital, New York City.
No. 9. New York City Hospital, New York City.
No. 10. Pennsylvania Hospital, Philadelphia, Pa.
No. 11. St. Joseph, St. Mary, and Augustana Hospital, Chicago.
No. 12. Northwestern University Medical School, Chicago.
No. 13. Presbyterian and Cook County Hospital, Chicago.
No. 14. St. Luke Michael Reese Hospital, Chicago.
No. 15. Roosevelt Hospital, New York City.
No. 16. German Hospital, New York City, United States only.
No. 17. Harper Hospital, Detroit, Mich.
No. 18. Johns Hopkins Hospital, Baltimore, Md.
No. 19. Rochester General Hospital, Rochester, N. Y.
No. 20. University of Pennsylvania Hospital, Philadelphia, Pa.
No. 21. Washington University Medical School, St. Louis, Mo.
No. 22. Milwaukee County Hospital, Milwaukee, Wis.
No. 23. Buffalo General Hospital, Buffalo, N. Y.
No. 24. Tulane University, New Orleans, La.
No. 25. Cincinnati General Hospital, Cincinnati, Ohio.
No. 26. Minnesota State University, Minneapolis, Minn.
No. 27. University of Pittsburg Medical School, Pittsburg, Pa.
No. 28. Christian Church Hospital, Kansas City, Mo.
No. 29. Medical School, University of Colorado, Denver, Colo.
No. 30. University of California, San Francisco, Cal.
No. 31. Youngstown Hospital, Youngstown, Ohio.
No. 32. City Hospital, Indianapolis, Ind.
No. 33. Albany Hospital and Medical College, Albany, N. Y.
No. 34. Episcopal Hospital, Philadelphia, Pa.
No. 35. Good Samaritan Hospital, Los Angeles, Cal.
No. 36. College of Medicine, Detroit, Mich.
No. 37. Kings County Hospital, Brooklyn, N. Y.
No. 38. Jefferson Medical School, Philadelphia, Pa.
No. 39. Yale Mobile Unit, Yale University, New Haven, Conn.
No. 40. Good Samaritan Hospital, Lexington, Ky.
No. 41. University of Virginia, University, Va.
No. 42. University of Maryland Medical School, Baltimore, Md.
No. 43. Emery University, Atlanta, Ga.
No. 44. Massachusetts Homeopathic Hospital, Boston, Mass.
No. 45. Medical College of Virginia, Richmond, Va.
No. 46. University of Oregon, Portland, Oreg.
No. 47. San Francisco Hospital, San Francisco, Cal.
No. 48. Metropolitan Hospital, New York City.
No. 49. University of Nebraska, Omaha, Nebr.
No. 50. University of Washington, Seattle, Wash.

4. These units were originally organized on a basis of 500 beds, but since have been expanded to 1,000 beds, as recommended by the commanding general, American Expeditionary Forces.

5. Base Hospitals Nos. 51 to 131 are in process of mobilization and will be ready for shipment overseas at an early date.

6. Ten base hospitals (venereal) were authorized on a 500-bed capacity, and the organization subsequently changed to 1,000 beds, at the request of the commanding general, American Expeditionary Forces. At the request of the chief surgeon American Expeditionary Forces, the special characterization of venereal hospitals was dropped, and they were organized under the dual request as 1,000-bed base hospitals without nurses. Seven have been organized. The personnel consists of 35 officers and 200 enlisted men.

7. Four special base hospitals have been organized:

Base Hospital No. 114, orthopedic.
Base Hospital No. 115, head.
Base Hospital No. 116, fracture.
Base Hospital No. 117, neuropsychiatric.

Nos. 114, 116, and 117 have been sent for duty overseas. No. 115 will be sent at an early date.

Base Hospital No. 102 has been organized in conjunction with the American Red Cross for service in Italy. It is now being equipped and will be sent over at an early date.

8. *Hospital units.*—Twenty-two hospital units have been formed, the preliminary organization of which was handled by the American Red Cross. These units were used to supplement the 500-bed base hospitals to bring them up to 1,000-bed organizations. The preliminary mobilization is as follows, except hospital unit "N" which was mobilized at General Hospital No. 5, Fort Ontario, N. Y., and was absorbed into the personnel of that unit:

A. Philadelphia, Pa. (Presbyterian Hospital), with Base Hospital No. 18, in France.
B. Yonkers, N. Y., with Base Hospital No. 23, in France.
C. Spokane, Wash., to report to Base Hospital No. 3, in France.
D. Louisville, Ky. (Louisville City Hospital), with Base Hospital No. 31, in France.
E. Richmond, Va. (Memorial Hospital).
F. New York City (Harlem Hospital), with Base Hospital No. 8, in France.
G. Syracuse, N. Y. (General Hospital, Syracuse), with Base Hospital No. 34, in France.
H. New York City (Fordham Hospital), with Base Hospital No. 9, in France.
I. Anderson, Ind. (St. John Hospital), to report to Base Hospital No. 1, in France. March 22, 1918.
K. Council Bluffs, Iowa, with Base Hospital No. 27, in France.
L. Pittsburg, Pa. (Allegheny General Hospital), with Base Hospital No. 24, in France.
M. Fort Wayne, Ind. (Hope Hospital).
N. New York City (Flower Hospital), Fort Ontario, N. Y.
O. Charlotte, N. C., with Base Hospital No. 6, in France.
P. Memphis, Tenn. (Memphis General Hospital), with Base Hospital No. 13, in France.
Q. Grand Rapids, Mich. (Butterworth-Blodgett University), to report to Base Hospital No. 20, France (at Fort McPherson, Ga., Mar. 30, 1918).
R. Fairfield, Iowa, with Base Hospital No. 32, in France.
S. Nashville, Tenn. (Vanderbilt University), with Base Hospital No. 17, in France.
T. Little Rock, Ark. (University of Arkansas), to report to Base Hospital No. 30, France (at Fort McPherson, March 30, 1918).
U. Burlington, Vt. (University of Vermont).
V. Dallas, Tex. (Baylor University), with Base Hospital No. 26, Fort McPherson.
W. Springfield, Ill. (St. John's Hospital), to report to Base Hospital No. 33, France (at Fort McPherson, Mar. 30, 1918).

9. *Evacuation hospitals.*—Sixty were authorized by indorsement, Adjutant General's Office, December 28, 1917. Nos. 1 to 24 have been organized, equipped, and trained at various camps. Of these, 8 are now on duty with American Expeditionary Forces.

10. *Evacuation ambulance companies.*—Twenty authorized by indorsement, Adjutant General's Office, December 28, 1917. Nine evacuation ambulance companies, each consisting of 1 officer and 37 enlisted men, have been organized and trained at the medical officers' training camps and at Camp Crane, Pa. Four are now on duty with American Expeditionary Forces. The organization of an evacuation ambulance company is as follows:

1 captain or lieutenant, Medical Corps.
3 noncommissioned officers.
3 mechanics.
2 cooks.
23 wagoners.
6 privates, first-class, and privates.

11. *Convalescent camps.*—Twelve were authorized by indorsement, Adjutant General's Office, December 28, 1917. Five camps, each consisting of 10 officers and 90 enlisted men, have been organized and trained at Medical officers' training camps. Two are now on duty with American Expeditionary Forces.

12. *Convalescent depots.*—One convalescent depot of five sections, A, B, C, D, and E, each section consisting of two officers and five enlisted men, have been organized and trained at the medical officers' training camp. Sections A and B are now on duty with the American Expeditionary Forces.

13. *Hospital trains.*—To comply with the request of the commanding general, American Expeditionary Forces, for personnel to man 50 hospital trains, the personnel of 34 trains (20 to 54, inclusive), which consists of 3 officers, 3 noncommissioned officers, 3 cooks, and 25 privates, have been organized at the two medical officers' training camps for overseas duty (indorsement, Adjutant General's Office, Dec. 28, 1917).

14. *Army sanitary trains.*—One Army sanitary train, motorized, of four sections, each section consisting of one ambulance company and one field hospital, has been authorized for overseas duty. Two sections have been organized and trained at the medical officers' training camps. One section is now on duty with the American Expeditionary Forces.

15. *Sanitary squads.*—Two sanitary squads for each division have been organized and accompanied their respective divisions overseas.

The sanitary trains for eight Infantry divisions, Regular Army, and one Cavalry division, Regular Army, consisting of 35 field hospitals and 35 ambulance companies, have been organized, equipped, and trained, and have accompanied their respective divisions overseas.

☛Forty-five Red Cross ambulance companies were enlisted in the Medical Enlisted Reserves, under authority from the War Department, dated July 30, 1917. Of these 45 companies, the personnel of 16 companies were transferred to the Medical Department under instructions from the War Department, dated July 2, 1917. The remaining 29 companies were assigned to sanitary trains of the National Army division, not more than two companies being sent to any one division.

Seventeen National Army divisions required 68 field hospitals and 68 ambulance companies to complete their sanitary trains. Twenty-nine ambulance companies being available in the Red Cross companies, it has been necessary to organize 68 field hospitals and 39 ambulance companies within these divisions. This has been done and these units are ready for overseas service.

The 17 National Guard divisions also required 68 field hospitals and 68 ambulance companies for their sanitary trains. The National Guard brought with them when drafted into the service 59 hospitals and 47 ambulance companies, many of which were incomplete in personnel, and all of which were incomplete in equipment. The other 9 field hospitals and 21 ambulance companies necessary to complete the National Guard sanitary trains have been organized within the divisions. This has been done, and these units are ready for overseas duty.

The following is a statement of division sanitary trains organized and ready for overseas duty (July 1, 1918):

1st Sanitary Train, 1st Division, Field Hospital and Ambulance Companies, Nos. 2 A. D., 3, 12, 13.
2d Sanitary Train, 2d Division, Field Hospital and Ambulance Companies, Nos. 1, 15, 16, A. D., 23.
3d Sanitary Train, 3d Division, Field Hospital and Ambulance Companies, Nos. 5, 7, 26, A. D., 27.
4th Sanitary Train, 4th Division, Field Hospital and Ambulance Companies, Nos. 19, 21, 28, A. D., 33.
5th Sanitary Train, 5th Division, Field Hospital and Ambulance Companies, Nos. 17, 25, 30, A. D., 29.
6th Sanitary Train, 6th Division Field Hospital and Ambulance Companies. Nos. 20 A. D., 37, 38, 40.
7th Sanitary Train, 7th Division Field Hospital and Ambulance Companies, Nos. 22 A. D., 34, 35, 36.
8th Sanitary Train, 8th Division Field Hospital and Ambulance Companies. Nos. 11, 31, 32, 43, A. D.
15th Sanitary Train, 15th Cavalry Division, Field Hospital and Ambulance Companies Nos. 10 A. D., 24 A. D., 39.
101st Sanitary Train, 26th Division Field Hospital and Ambulance Companies, Nos. 101, 102, 103, 104.
102d Sanitary Train, 27th Division Field Hospital and Ambulance Companies Nos. 105, 106, 107, 108, A. D.
103d Sanitary Train, 28th Division Field Hospital. Nos. 109, 110, 111, A. D., 112. Ambulance Companies Nos. 109 A. D., 110, 111, 112.
104th Sanitary Train, 29th Division, Field Hospital Nos. 113, 114, 115, 116, A. D. Ambulance Companies Nos. 113, 114, A. D., 115, 116.

105th Sanitary Train, 30th Division Field Hospital and Ambulance Companies Nos. 117, 118, 119, 120, A. D.

106th Sanitary Train, 31st Division, Field Hospital and Ambulance Companies Nos. 121, 122, 123, 124, A. D.

107th Sanitary Train, 32d Division, Field Hospital and Ambulance Companies Nos. 125, 126, 127, 128, A. D.

108th Sanitary Train, 33d Division, Field Hospital and Ambulance Companies Nos. 129, 130, 131, 132, A. D.

109th Sanitary Train, 34th Division, Field Hospital and Ambulance Companies Nos. 133, 134, 135, 136, A. D.

110th Sanitary Train, 35th Division, Field Hospital and Ambulance Companies Nos. 137, 138, 139, 140, A. D.

111th Sanitary Train, 36th Division, Field Hospital and Ambulance Companies Nos. 141, 142, A. D., 143, 144.

112th Sanitary Train, 37th Division, Field Hospital and Ambulance Companies Nos. 145, 146, 147, 148, A. D.

113th Sanitary Train, 38th Division, Field Hospital and Ambulance Companies Nos. 149, 150, 151, 152, A. D.

114th Sanitary Train, 39th Division, Field Hospital and Ambulance Companies Nos. 153, 154, A. D., 155, 156.

115th Sanitary Train, 40th Division, Field Hospital and Ambulance Companies Nos. 157, 158, 159, 160, A. D.

116th Sanitary Train, 41st Division, Field Hospital and Ambulance Companies Nos. 161, 162, 163, 164, A. D.

117th Sanitary Train, 42d Division, Field Hospital and Ambulance Companies Nos. 165, 166, 167, 168, A. D.

301st Sanitary Train, 76th Division, Field Hospital and Ambulance Companies Nos. 301, 302, 303, 304, A. D.

302d Sanitary Train, 77th Division, Field Hospital and Ambulance Companies Nos. 305, 306, 307, 308, A. D.

303d Sanitary Train, 78th Division, Field Hospital and Ambulance Companies Nos. 309, 310, A. D., 311, 312.

304th Sanitary Train, 79th Division, Field Hospital and Ambulance Companies Nos. 313, 314, 315, 136, A. D.

305th Sanitary Train, 80th Division, Field Hospital and Ambulance Companies Nos. 317, 318, A. D., 319, 320.

306th Sanitary Train, 81st Division, Field Hospital and Ambulance Companies Nos. 321, 322, A. D., 323, 324.

307th Sanitary Train, 82d Division, Field Hospital and Ambulance Companies Nos. 325, 326, 327, 328, A. D.

308th Sanitary Train, 83d Division, Field Hospital and Ambulance Companies Nos. 329, 330, A. D., 331, 332.

309th Sanitary Train, 84th Division, Field Hospital and Ambulance Companies Nos. 333, 334, 335, 336, A. D.

310th Sanitary Train, 85th Division, Field Hospital and Ambulance Companies Nos. 337, 338, 339, 340, A. D.

311th Sanitary Train, 86th Division, Field Hospital and Ambulance Companies Nos. 341, 342, 343, 344, A. D.

312th Sanitary Train, 87th Division, Field Hospital and Ambulance Companies Nos. 345, 346, 347, 348, A. D.

313th Sanitary Train, 88th Division, Field Hospital and Ambulance Companies Nos. 349, 350, A. D., 351, 352.

314th Sanitary Train, 89th Division, Field Hospital and Ambulance Companies Nos. 353, 354, 355, 356, A. D.

315th Sanitary Train, 90th Division, Field Hospital and Ambulance Companies Nos. 357, 358, 359, 360 A. D.

316th Sanitary Train, 91st Division, Field Hospital and Ambulance Companies Nos. 361, 362, A. D., 363, 364.

317th Sanitary Train, 92d Division, Field Hospital and Ambulance Companies Nos. 365, 366, 367, 368, A. D.

318th Sanitary Train, 93d Division, Field Hospital and Ambulance Companies Nos. 369, 370, 371, 372.

319th Sanitary Train, 94th Division, Field Hospital and Ambulance Companies Nos. 373, 374, 375, 376.

5. SECTION OF SELECTION, CONSTRUCTION AND REPAIRS.

A. STATUS AT CLOSE OF FISCAL YEAR 1917.

1. At the close of the fiscal year on June 30, 1917, there were about 10,000 hospital beds, distributed as follows:

Army posts	5,100
General hospitals	1,700
Base hospitals along the Mexican border about	3,400

2. The character of construction of the post hospitals referred to is well known to be usually of brick or concrete and of the permanent type construction. The character of construction in the general hospitals was similar and they differed mainly in size and in the grouping of buildings and the more elaborate installation of surgical and medical appliances and specialties. The character of construction in the base hospitals along the border was temporary in type, consisting of frame buildings usually ceilled and mostly heated by stoves and with scant plumbing.

B. THE WORK OF FISCAL YEAR 1918.

1. At the opening of this fiscal year, beginning July 1, 1917, the plans prepared for the hospitals for the National Army and National Guard camps were being turned over to the Quartermaster Department for execution. These plans as prepared in the Surgeon General's office were working drawings only, such as have always been prepared in this office. Some construction detail was gone into, but in the main the plans were working drawings quite free from detail as to wiring, plumbing, heating, sewer lines, lighting, etc., yet were comprehensive enough to serve in the field as construction drawings for the temporary character of construction which they represented. Due to the antiquated printing apparatus in the construction branch of this office, there was some delay experienced in printing the large numbers of plans required in the field for erection purposes, and it was necessary for weeks to run the printing machine 21 hours per day and demand overtime labor with no increase of pay possible. Therefore a modern motor-driven printer and a motor-driven gas-heated drier were installed. Some blue printing was done by outside firms, but this method was slow, costly, and generally very unsatisfactory. The majority of the printing firms were constantly well stocked with work due to the various Government construction activities which found it feasible to turn over for printing a certain class of work.

2. As above referred to, the character of these hospital buildings was temporary, yet differed materially from the temporary hospital construction at the so-called base hospitals on the border, in that there was more plumbing installation, there were central heating plants usually, and the hospitals were provided with sewage disposal systems.

3. In the preparation of these plans medical officers representing the various services and specialties, such as surgery, medicine, laboratory, eye, ear, nose, and throat, dental, X-ray, nervous, and mental, were consulted, and as far as time, necessary construction, standardization, and funds permitted plans were worked up to embody the essential features desired. These features were incorporated with other usual hospital features and activities and a general plan was thus evolved for the so-called typical 1,000-bed hospital. A 500-bed hospital was drawn by a similar process. In order to standardize equipment, materials, personnel, construction, and administration problems as much as possible, it was thought best to do this, and the 1,000-bed and the 500-bed types were thought to comply with the majority of conditions. The 500-bed hospital differs from the 1,000-bed hospital not only in the number of wards, which are the same in type, but in the size of the administration building, receiving building, general mess hall, kitchen, and certain other service features.

4. There were certain differences between National Army and National Guard hospitals as constructed. The National Army hospitals were built with central steam-heating plants, the buildings were lined throughout with wall board, and there was plumbing and sewage. The National Guard hospitals were without these features and the buildings were constructed with a somewhat lower clearance overhead. Both the National Guard and the National Army buildings had ridge ventilation from end to end. Later on, changes were made in the type of ventilating device to reduce cost and construction time. A modified ridge ventilator, full length of buildings, was adopted, which was inexpensive, easy to construct, and which so far has proven satisfactory. The differences in construction between the National Army and the National Guard hospitals was the result of instructions from higher authority based on the assumption that the National Guard camps where the National Guard

hospitals were located would not exist in the winter. This, however, did not prove to be the case. Requests had been made for interior lining and for plumbing and sewage, and late in the fall, too late for health, comfort, and economical installation, these necessities were authorized and installation began.

5. Table 151 shows briefly the average schedule of buildings for a so-called 1,000-bed hospital.

TABLE NO. 153.—*Average schedule of hospitals.*

Title.	Use.	Number of buildings.
Schematic hospital plan	Guide to quartermaster of desired arrangement	
Administration building	Administrative offices, dispensary	1
Officers' ward	Ward, kitchen, and mess for sick officers	1
Staff quarters	Quarters for hospital staff officers	1
Officers' quarters	Quarters, kitchen, and mess for medical officers on duty in hospital.	1
Nurses' quarters	Quarters, kitchen, and mess for nurses on duty	1
Laboratory and X-ray building	Laboratory and X-ray work	1
Eye, ear, nose, and throat and dental building.	Operating rooms and other features for these specialties.	1
Operating pavilion	All operating except that done in F-1	1
Hospital exchange	For hospital exchange, amusement, barber shop, etc.	1
Garage	For authorized hospital transportation	1
General mess and kitchen	Kitchen and mess hall for general use of enlisted sick and other sick not included in other messes.	1
Reception building	Reception and registration of admitted cases and storage of their effects; for their discharge as well.	1
Common single ward	For general sick	16
Common double ward	do	8
Isolation ward	For small groups of contagious cases	3
Medical Department enlisted men's barracks.	Barracks, toilet, and day room for enlisted personnel of hospital.	6
Medical Department enlisted, kitchen and mess.	Kitchen and mess hall for Medical Department men and others on duty not messed elsewhere.	1
Storehouse	For camp medical supply depot and for storage space for hospital.	4
Mortuary	For post-mortem work, preparation and viewing of the dead.	1
Chapel	For religious services and amusements	1
Laundry building	For storage and handling of linen and for future adaptation for laundry washing; also for disinfection purposes.	1
Psychiatric ward	For mental and nervous diseases	1

6. It was desired to provide hospital space for over 3 per cent of the command for which the hospital was to serve, but this was not authorized. This was, however, offset in a measure by the installation of certain corridors and porches. This was most fortunate, as was proven later in the winter before the general enlargement of these hospitals was authorized.

7. There was a shortage of competent draftsmen and designers throughout the remainder of the calendar year 1917, and it still exists to-day. It was, however, necessary at this period to increase the drafting force. This was rendered difficult because the Civil Service Commission was not able to supply draftsmen and the law does not permit this office hiring draftsmen except at a very low figure. This state of affairs rendered the commissioning of draftsmen about the only means by which this office could secure competent service. The circumstances almost warranted this recourse, which, however, was not resorted to. Architects, however, versed in hospital design and construction or in military procedure were commissioned in the Sanitary Corps for supervising duties. By considerable effort and after extended delays the drafting and designing force was organized and all hospital plans were studied and restudied and revised as occasion demanded. In justice to the draftsmen secured, it should be said that they have worked faithfully and have without hesitation put in many hours and days overtime. When one considers the fact that they are underpaid for this class of work to-day, every credit should be given them.

8. The problem of hospital construction comprehended (*a*) the enlargement of existing post hospitals to meet the demands of increased garrisons, especially at coast artillery posts and recruit depots; (*b*) the construction of hospitals at every National Army and National Guard camp and all other training camps; (*c*) the construction of hospitals for the embarkation camps; (*d*) construction of hospitals for miscellaneous military activities, such as arsenals, filling plants, proving grounds, depots, etc.; (*e*) the construction of new general hospitals; (*f*) debarkation hospitals; (*g*) and certain special hospitals which for purposes of administration are classed as general hospitals.

9. During the execution of this work considerable expansion took place. At the beginning 5 civilian employees were engaged in the work under the supervision of 1 officer who had other activities as well. There are now 18 officers and civilian employees engaged on the technical and administrative work of this branch. The velume of work done is much greater proportionately than the increase in personnel. In this year it has been possible to bring the construction branch in direct physical contact with the hospital division of the Surgeon General's Office, which has been a great step forward. If the Surgeon General's Office is to continue to prepare working drawings of desired construction, this consolidation should continue. The blueprinting plant is separated, and this should not be, but it is now not possible to consolidate further.

10. For the fiscal year which ended June 30, 1918, the Congress appropriated $750,000 for construction and repair of hospitals at military posts already established and occupied, and gave authority to use, from the above sum, $25,000 to erect a new hospital at Fort Ward, Wash.; $100,000 to build a modern hospital at Schofield Barracks, Hawaii; $90,000 to enlarge the Walter Reed General Hospital; $90,000 to erect a modern hospital at Fort McPherson, Ga.; and $60,000 to build an officers' infirmary for the general hospital, Fort Bayard, N. Mex. The hospitals at military posts have been kept in repair, but, owing to the necessity for funds to use in constructing temporary hospital buildings rendered necessary on account of the war, it was impossible to construct the new buildings authorized by Congress, and the funds were used to construct temporary buildings; therefore it will be necessary for Congress to renew the amounts stated before the above-mentioned hospitals can be constructed. Congress also appropriated $25,000 for the current fiscal year for construction and repair of quarters for hospital stewards at military posts already established and occupied. These funds have been used for the purpose for which they were authorized, and the quarters are in fairly good condition so far as repairs are concerned, but some general hospitals and some military posts are in much need of such quarters. Deficiency appropriations for 1918 have been approved by Congress for construction and repair of hospitals, as follows:

Oct. 6, 1917	$35,000,000.00
Mar. 28, 1918	19,654,300.00
July 8, 1918	13,936,554.66
Total	68,590,854.66

The last deficiency estimate presented to Congress for $13,000,000, while not gaining approval till after the close of the fiscal year, will nevertheless be used for projects conceived and in some cases completed prior to the close of the fiscal year. This money will be available until December 31, 1918.

11. Many hospitals as they now stand have been added to several times since they were originally hastily planned. It seems quite likely that this unsatisfactory practice must continue, and may even be extended to the majority of the camp and cantonment hospitals, as many camps will probably be increased in size. It was necessary last winter to increase the size of all the camp and cantonment hospitals, but this increase was not due to an increase in the size of the camps. It was rendered necessary because the hospitals as authorized were not quite large enough to care for the percentage of men which it was found advisable to treat and segregate away from their organizations.

12. In addition to hospital construction proper a regimental infirmary was erected for each regiment or separate unit of similar size. Also one and sometimes two large dental infirmaries were built in each camp and cantonment. It has also been necessary to construct in the camps at the ports of embarkation hospital space in excess of that usually necessary at other camps. Eight per cent of troops passing through New York pass through the embarkation hospitals there. These are not to be considered with general hospitals.

13. Aside from the construction of hospitals, regimental infirmaries, dental infirmaries, quarantine camps, etc., all associated with troops in post or in camp, it has been necessary to construct from this fund other hospitals for the care of the sick who may not properly be cared for at existing post hospitals of the United States or at the camp base hospitals. These cases may be called "general" cases, and require what may be called general-hospital beds. Therefore, for the care of the cases that should no longer be retained in camp base hospitals and for the care of those returning from overseas, additional general hospitals were constructed. This work is still going on, and it has been so planned that each month enough general-hospital beds will be added to keep abreast with the incidence of that class of sick. It is planned to establish in each draft district one or more of these hospitals as occasion demands. In such as may be located appropriately reconstruction facilities are being provided.

IV. MEDICAL AND HOSPITAL SUPPLIES.

1. GENERAL.

At the declaration of war the department was confronted with the task of furnishing supplies and equipment vastly in excess of the requirements in time of peace. The stock of supplies on hand was sufficient to meet the needs of an Army of approximately 300,000. Estimates had to be prepared, purchases authorized, a distribution system devised, additional warehouses secured, depots established, and a force of sufficient magnitude to handle the situation secured.

In the Army appropriation act for the fiscal year 1918, approved May 12, 1917, $1,000,000 were appropriated for the Medical Department. The act of June 15, 1917, appropriated $29,780,000 additional. These sums proving inadequate, an appropriation of $100,000,000 was made October 6, 1917, and a further deficiency appropriation of $33,000,000 was made July 8, 1918.

On July 21, 1917, the sections of the office handling disbursements, administrative audit of vouchers, and property returns were consolidated into the finance and supply division. This division is charged with all matters pertaining to the procurement and issue of Medical Department supplies and the administrative audit of all vouchers in payment therefor, as well as for services rendered the department.

On July 1, 1917, the department had in operation in the United States medical-supply depots at New York City, Washington, St. Louis, San Antonio, and San Francisco. Four new depots at Atlanta, Chicago, Louisville, and Philadelphia were being stocked. It was early seen that with the establishment of the various camps would come the need for the development at each of a local depot equipped to meet all the needs of the camp, regimental organizations, sanitary trains, and the base hospital. It became necessary to find trained personnel to purchase, inspect, supervise transportation, issue, and account for the varied supplies so necessary for the proper care and treatment of the sick. Additional officers and personnel were required for the distributing depots. Officers for the various camp medical-supply depots had to be found, commissioned, and transported to the scene of their future activities before the arrival of the supplies, which in turn had to reach the camp before the arrival of troops. In many instances supplies arrived at the camps before buildings were ready to receive them. They were stored wherever space could be secured in farm buildings, in the open, or under canvas. Every medical-supply officer of the camps had to adapt himself to existing conditions and remain on duty not infrequently the whole 24 hours if need be, for he was the only representative of the Medical Department present to care for the supplies. With the arrival of troops, enlisted personnel were detailed to duty in the improvised depots, and conditions improved. As time passed, the needed storehouses were completed and the camp medical-supply depots were stocked and in full operation.

The Sanitary Corps was authorized June 30, 1917, to provide technical and nonmedical personnel for the various activities of the Medical Department. This corps made it possible to obtain officers for duty as supply officers, purchasing agents, X-ray technicians, automobile and accounting experts, and provided for the development of an adequate personnel for the supply service. Sixteen officers of the Medical Corps have been on duty with the supply service; 331 officers of the Sanitary Corps were commissioned for duty with that service, and 1,471 enlisted men are on duty in the various supply depots at home and abroad, of which 425 are with special units. The best obtainable men have been selected for this service, and the greatest care taken to eliminate the unfit to the end that those selected may be able to endure the hardships and vicissitudes of active campaign.

Training schools have been established and every effort made to insure that each officer, noncommissioned officer, and private is fully qualified before he is assigned to duty. Of the 331 officers of the Sanitary Corps now engaged in supply work 288 have risen through the various grades of private and noncommissioned officer to officer.

A surgical-instrument repair unit, consisting of one officer and 89 enlisted men, equipped with all the machinery and material necessary to repair and make, if necessary, any of the instruments in use, is now in France.

A motor-ambulance assembly unit, composed of 3 officers and 68 enlisted men who had been carefully selected from all of the important automobile plants in the United States, was sent to France in February. This was followed by an accounting and auditing unit of the Medical Department, which has 6 officers and 135 enlisted men, which has been intrusted with the finance and property accountability of the Medical Department overseas. Later an optical shop, with 2 officers and 25 enlisted men, and still other lesser units were sent, making a total as above. Additional men are being supplied from time to time.

2. SUPPLY DEPOTS.

The requirements for storage space for the reception and issue of supplies increased so rapidly that new buildings had to be added from time to time. By the end of the year storage space available in the depots was as follows:

	Square feet.
Atlanta, Ga	146,000
Chicago, Ill	177,000
Louisville, Ky	45,000
New York City	185,000
Philadelphia, Pa	192,000
St. Louis, Mo	347,000
San Antonio, Tex	48,000
San Francisco, Cal	112,000
Washington, D. C	270,000
Total	1,522,000

There are also in operation overseas embarkation warehouses at New York City and Newport News, Va. The former is on Pier 45, North River, and has 80,000 square feet of floor space; the latter is in Government-owned buildings having 50,000 square feet of floor space.

During the period November 25, 1917, to June 30, 1918, there were shipped to the expeditionary forces in France 31,099 tons of Medical Department supplies, occupying a total space of 3,771,810 cubic feet.

All the depots were satisfactorily housed by the end of the year except San Antonio, where the supplies still remain stored in a number of small buildings scattered over a large area, making administration and the prompt handling of and efficient accounting for supplies at that depot very difficult. The St. Louis depot is also in buildings scattered over a wide area and its proper coordination rendered difficult thereby.

The New York depot has been used as a procurement depot for post supplies; the field medical supply depot at Washington, for the procurement of field supplies and for the assembling of field units; and the depot at St. Louis for the procurement of veterinary supplies and for the assembling of veterinary field units. In addition to the purchase and assembling of veterinary equipment, the St. Louis depot has been utilized as the distributing depot for post and field supplies to the States of Oklahoma, Colorado, Kansas, Missouri, Arkansas, Louisiana, and Mississippi. The Chicago depot distributes supplies to the States of Montana, Wyoming, North and South Dakota, Michigan, Minnesota, Iowa, Wisconsin, Indiana, Ohio, and Kentucky. The Philadelphia depot supplies the States of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, New Jersey, Maryland, Delaware, and Virginia. The Atlanta depot distributes supplies to the troops stationed in North Carolina, South Carolina, Georgia, Florida, Alabama, and Tennessee. The depot at San Antonio distributes supplies to Texas, New Mexico, Arizona. The depot at San Francisco is the distributing point for the States west of the Rocky Mountains, including Idaho, Nevada, and Utah. The Louisville depot handles only motor ambulances, motorcycles, spare parts, trailers, and miscellaneous spare parts for all such equipment for all stations in the United States.

The subsidiary supply depots established at all camps and cantonments have met the requirements of the service satisfactorily and have been efficiently operated, although considerable confusion existed during the first few months. Considering the congestion of the railway traffic, the confusion incident to the rapid expansion of the hospitalization at camps, and the lack of knowledge of military matters, methods and regulations on the part of medical officers and enlisted personnel, the delivery of medical supplies to all organizations was efficiently performed as could have been expected during the trying period immediately following the mobilization of troops. All these depots are now completely equipped and no difficulty is anticipated in keeping them supplied during the coming year.

3. MEDICINES.

By judicious methods of procurement, an ample supply of drugs has been obtained with the exception of a few alkoloid substances, such as atropine and homatropine, of which the supply is limited and difficult to secure. The importation of digitalis from abroad has been superseded by domestic production and a standardized tincture has been prepared through the courtesy and efforts of Prof. F. J. Wulling, College of Pharmacy, University of Minnesota.

The production of arsphenamine has been improved and increased until the supply is nearly sufficient to meet the demands. The toxicity of the domestic product has been so reduced that the best grades equal or excel the German salvarsan imported prior to 1914.

4. BLANK FORMS.

As was expected from the great expansion of the Medical Department and from the inexperience of the personnel, enormous quantities of blank forms have been used. Resort to private printers was necessary to meet a large part of this demand. The increased range of activities of the Medical Department has required the adoption of a few additional forms, but, as a whole, the standard forms in use have proved satisfactory and sufficient to meet the requirements. The field medical supply depot in Washington is the distributing depot for these blank forms. Shipments are made in bulk to the main distributing depots and to the camp medical supply depots. From these distribution is made to the hospitals and other units in their respective areas.

5. SURGICAL DRESSINGS.

During the early part of the year contracts for vast quantities of supplies were entered into with the existing dressing manufacturers. As time passed it became necessary, in order to maintain the supply, for the Government to procure the gray goods from the mills and furnish to the dressing manufacturers such quantities as they could handle and have the remainder bleached and finished wherever possible. During the year 28,776,000 yards of absorbant gauze, 34,000,000 sublimated gauze packets, 60,119,200 compressed bandages, 62,746,127 roller bandages, 8,423,580 first-aid packets, 10,000,270 individual packets, and 600,000 shell-wound packets were produced and delivered.

Arrangements for the preparation of large quantities of surgical dressings have been made with the American National Red Cross. The Medical Department furnishes all the materials and the various chapters of the Red Cross make up the dressings. Many thousands of such dressings have been sent abroad.

The Red Cross has also rendered valuable service by making such articles as nightshirts, operating gowns, pajamas, etc., from materials furnished by the Medical Department.

6. SURGICAL INSTRUMENTS.

The procurement of a sufficient number of surgical instruments has been the most difficult of the supply problems. Since the bulk of all surgical instruments in use in the United States was imported either from Germany or from England before the war and since this source of supply was closed by the war, it became necessary to call upon domestic surgical instrument manufacturers for greatly increased production, and to develop new sources of supply. As a result of the campaign for this development, surgical needles, the entire supply of which was formerly imported, are now obtained in sufficient quantities and of satisfactory quality from domestic sources. Toolmakers, cutlery manufacturers, and jewelers are contributing to increase the supply of forged and finished instruments. Standardization of surgical instruments supplied to the Army has made possible this increased production. While the demands for the coming year will undoubtedly be many times greater than those of the year just closed, new sources of supply in sufficient numbers have been developed to insure an adequate quantity of all needed instruments. Organizations and manufacturers which have never made surgical instruments have responded to the call and are to-day making better instruments than those formerly imported from Germany.

7. WARD EQUIPMENT.

During the year 251,628 bedsteads and full equipment therefor were procured and distributed. Thirty-five base hospitals were established at camps and the equipment for 32 additional was sent abroad. The major portion of the equipment for these 32 hospitals sent abroad was supplied by the Red Cross. Also 26 general and other large hospitals were equipped at home.

Pursuant to cable requests from overseas, the equipment of base hospitals now sent abroad has been increased to accommodate 1,000 patients with the crisis expansion of an additional 1,000. The complete equipment of one such hospital, including steam sterilizer and portable disinfector, weighs 150 tons and occupies over 30,000 cubic feet of space. Evacuation hospitals have likewise been increased to a capacity of 1,000 patients, and the equipment of 10 such has been forwarded overseas. Fifteen evacuation hospitals equipped according to Manual for the Medical Department were also sent in the early part of the year.

8. GAS MASKS.

By direction of the Secretary of War, under date of May 16, 1917, the development and production of gas masks was made a function of the Medical Department. It became necessary at once to provide an organization of trained personnel for this special purpose. This organization was developed as a part of the Sanitary Corps. At the close of the year it consisted of 186 commissioned officers and 1,199 enlisted men. To it was assigned the duty of supplying not only gas masks for both men and horses, but chemical sprayers for cleaning trenches, oxygen apparatus for resuscitating the wounded, trench fans, and gas samplers. The service was divided into the field supply section, overseas section, and training section.

The training section has been transferred to the control of the Engineer Corps. The duties of this section were to advise and help the division staff officers in the handling of masks, the handling of gas used for training purposes, the disinfection of masks used for training purposes, and the training of officers in the use of gas-sampling apparatus, gas detectors, and other means of defense against gas.

The field supply section of the gas-defense service is roughly divided into the technical division, the procurement division, the inspection division, and the controlling division. The duties of the field supply section have been the superintending of purchase, manufacture, and inspection of gas masks and similar appliances for the United States Army. A list of the articles which it supplies includes trench fans, chemical testing tubes, vacuum bottles, glass jars for making analysis of gas, weather vanes, special overalls and suits for protection against certain gases, special gloves for handling articles which may come in contact with dangerous chemicals, and a specially prepared paste which is rubbed on the body to protect it against various gases. It also provides supplies for the training camps, such as gas bombs, smoke boxes, and various articles for carrying on mimic gas warfare.

After the failure of many efforts to obtain a sufficiently rigid inspection to secure a high quality of production, it became necessary to establish a plant entirely under the control of the gas-defense service for assembling into completed masks the various parts produced by private manufacturers. On November 20, 1917, authority was obtained from the Secretary of War for the establishment of such a plant in Long Island City, N. Y. This plant is operated by the gas-defense service and at the present time has a total of 4,691 civilian employees.

The articles which this section supplies are not standard articles procurable in commercial markets, but are specially designed and manufactured or contracted for by the gas-defense service and assembled either in the gas-defense plant or in various plants under the direct supervision of the gas-defense service.

Since the gas-defense service was established, up to and including June 30, 1918, it has produced 262 specially impregnated suits of oiled clothing, 354 pairs of oiled gloves, 1,199 oxygen inhalators, 11,103 trench fans, 120,000 tubes sag paste, 154,094 horse masks, 502,898 extra canisters for gas masks. It has manufactured a total of 1,718,632 gas masks, of which 1,432,224 have been delivered to the quartermaster at the port of embarkation for shipment overseas. The balance have been used for experimental and training purposes in the United States.

9. MOTOR AMBULANCES.

A special organization has been developed for the purchase, production, inspection, and maintenance of motor ambulances, motorcycles, spare parts, and equipment. This work has been under the direction of automobile and business experts, and has included a directing officer in Washington, D. C.; a motor ambulance experimental station, Washington, D. C.; a motor ambulance supply depot, Louisville, Ky.; a motor ambulance assembly base, American Expeditionary Forces; and stations for inspection and testing ambulance chasses, ambulance bodies, spare parts trailer chasses and bodies, motorcycles, etc., at each plant in the United States where they have been produced.

In addition to the procurement, production, and inspection of motor ambulance equipment, a new design of knockdown ambulance body has been developed and put into production, the standard ambulance chassis has been improved in spring suspension, shock absorbers, starting of engine, driver's apron and windshield, draining of cooling system, radiator support, and several motor details. A special "spare parts A" equipment for each ambulance has been provided, and a "spare parts B" equipment, together with a special spare parts trailer, to be carried with each ambulance company, and designed to take care of all except major repairs and accidents in service. A book of "Information and Instructions" covering equipment, spare parts, repairs, and maintenance for United States standard motor ambulances and United States standard motorcycles in the service of the Medical Department, United States Army, has been compiled and distributed, which includes lists of all equipment, spare parts, etc., as well as directions for the inspection of ambulances by drivers and mechanics, and instructions for assembling, adjustment, and maintenance of each ambulance chassis unit. A supply, repair, and salvage depot has been established at Louisville, Ky., for the upkeep of ambulances and motorcycles in the United States.

Tentative drill regulations for the United States standard closed ambulance have been published and distributed.

Two types of litter carriers have been designed: (1) A hospital wheeled litter carrier, which is light in weight, cheap, easily knocked down and boxed for overseas shipment and readily assembled by inexpert mechanics. A special rest readily converts the carrier into a temporary operating table; (2) a field litter carrier, which enables two litter bearers to handle two wounded on litters, and which may be used in a trailer behind the standard motor ambulance.

10. RÖNTGENOLOGY.

When the United States entered the war two problems with regard to X-ray work presented themselves. One was to train a sufficient number of Röntgenologists and the other to furnish suitable apparatus in sufficient quantity.

The problem of training Röntgenologists was met by establishing nine different schools in as many cities, in charge of officers of the Medical Reserve Corps. Later the instruction work was concentrated at Cornell Medical College, in New York City, with two schools for preliminary instruction at the medical officers' training camps at Fort Oglethorpe and Fort Riley. About 500 officers of the Reserve Corps have been trained in these schools for duty as military Röntgenologists, most of whom are serving as such at military hospitals in this country or abroad. Based on French experience, it will be necessary to furnish at least 600 Röntgenologists for each 1,000,000 of troops. This will make it necessary to continue the courses of instruction as long as the war lasts.

It is also necessary to train enlisted men as X-ray manipulators to do the photographic and other routine work in X-ray laboratories. These are needed in the proportion of two to each Röntgenologist. A large number have now been trained.

The following new apparatus has been devised or adopted by the Medical Department during the past year:

(1) An X-ray table designed for use with both portable and stationary outfits and satisfactory for both Röntgenoscopic and Röntgenographic work. This table with the X-ray box and tube stand detached has also been adopted by the surgical division as an operating table for mobile surgical units.

(2) A bedside X-ray unit which makes it possible to do satisfactory X-ray work on any part of the body without removing the patient from his bed.

(3) A portable X-ray apparatus for use at forward hospitals and other places where there is no electric current. This apparatus consists of a specially modified Delco gas-electric set, which furnished alternating current to a high-tension transformer. For both this apparatus and the bedside unit Dr. Coolidge has devised a special radiator type of Coolidge tube which rectifies its own current, thus eliminating moving parts from the apparatus. A 50-foot cable makes it possible to place the engine at that distance from the X-ray table. The standard Army ambulance has been modified by removing the seats and making a few simple additions so as to carry the complete portable outfit and one bedside unit.

(4) A complete set of apparatus for localization of foreign bodies has been adopted. This contains instruments for the application of the following methods:

(*a*) Two-wire double tube-shift method.
(*b*) Parallax method.
(*c*) Tube-shift method with mechanical triangulation.
(*d*) Profondometer.
(*e*) Hirtz compass with accessory devices.
(*f*) Canula and trocar with harpoon.

A sufficient quantity of X-ray apparatus and supplies of all kinds has been shipped abroad for use of both stationary and mobile hospitals with the American Expeditionary Forces. X-ray apparatus has also been furnished in adequate quantity for military hospitals in the United States.

11. VACCINES AND BIOLOGICALS.

Triple typhoid vaccine for the entire military force has been furnished promptly and efficiently by the Army Medical School.

By agreement with the commercial biological producers the territorial limits of the United States were divided into districts and every producer given a definite area to supply with such products as he was best able to furnish. Smallpox vaccine was delivered to every camp and concentration point in ample quantity prior to the arrival of the first increment of the draft, and the stock has been replenished at intervals in time to meet the requirements of each succeeding increment of the draft. During the months of incidence of pneumonia and meningitis large quantities of antipneumococcic and antimeningitis serum were supplied. Part of this serum was obtained from the Rockefeller Institute, from the New York State Board of Health, and from the New York City Board of Health. The sera produced by these scientific bodies was considered a standard, and efforts to induce the biological producers to raise their standards to conform to the same requirements were successful. Before the end of the year, the hygienic laboratory of the Public Health Service had arranged to examine samples of all lots of sera and other biological products before they were placed on the market, whether for military or civilian use.

During the epidemic of pneumonia and meningitis the various biological producers were invited to send representatives to the camps with a view to obtaining and incorporating in the immunization of their horses such new strains as might be found. A few strains which do not conform to known types were found and have been utilized in the preparation of immune serum. With this cooperation between the Army, Public Health Service, and biological producers standardized sera are now available for civilian as well as military use.

V. DIVISION OF LABORATORIES AND INFECTIOUS DISEASES.

This division was organized in June, 1917, and was divided into sections, as follows: Section of laboratories and infectious diseases, exclusive of venereal diseases; section of combating venereal diseases; and section of urology and dermatology.

The reports of these three sections are presented separately.

1. THE SECTION OF LABORATORIES AND INFECTIOUS DISEASES.

To this section was delegated the task of furnishing trained personnel, supervising and directing the laboratory service of the Medical Department, and instituting measures for the prevention and control of infectious diseases. The problem of infectious diseases, particularly pneumonia and meningitis, has necessitated numerous extensive investigations by groups of experienced epidemiologists, bacteriologists, and pathologists. The result of these investigations has materially added to our knowledge of the methods of combating these diseases.

A laboratory manual has been compiled for the use of officers, which describes standard methods of laboratory procedure. The rapid advances in methods of laboratory diagnosis during the publication of this work and the appearance of new problems has necessitated an immediate revision, which is now well under way.

At the beginning of the activities the laboratories of the Army capable of doing comprehensive work were six, viz, the laboratories of the Central, Southern, Philippine, and Hawaiian Departments, Letterman General Hospital, and the Army Medical School, with an officer personnel of about 12. At the present time there are 110 completely equipped laboratories in the United States capable of doing all kinds of laboratory work independently, and the personnel in all laboratories and under instruction July 1 was about 1,000.

The Rockefeller Institute in New York City has been organized under the director as an Army laboratory and training school. A full report of the activities of this institution is presented in another section of this report.

A school for laboratory officers, started at the Central Department laboratory, has been transferred to buildings at Yale University, made available through the generosity of Yale University. This school was necessitated by the inadequate supply of medical officers trained in laboratory work, and by the demand for large numbers of enlisted men trained in technical work for laboratories of the enlarged Army. Yale University has further helped this school by the building of a temporary structure at a cost of over $35,000.

The Army Medical School has also established classes for training officers and enlisted men, so that at the present time three schools of instruction for laboratory men are operating under this division.

It has been necessary to take scientific men and perfect them in laboratory methods and commission them in the Sanitary Corps to replace medical officers in our laboratories. This has been one function of the Army Medical and Yale Army laboratory schools, and the present shortage of medical officers with any training whatsoever along laboratory lines will necessitate the training of considerable numbers of nonmedical men for this purpose.

Women physicians are being placed on duty as contract surgeons, and with the aid of the medical division of the National Research Council 10 schools have been established and courses standardized for the training of nonmedical women as laboratory technicians. One hundred and twenty-five trained women technicians are now (July 1) on duty in the laboratories in this country, replacing men for overseas service.

It has been found necessary in all camps to more than double the laboratory capacity in order to handle the large amount of work necessitated by the occurrence of infectious diseases. Large numbers of examinations for meningococcus, diphtheria, and other carriers have been made, and a great deal of investigation in epidemiology has been necessitated by the considerable numbers of cases of pneumonia, meningitis, and infections by the hemolytic streptococcus. Reports on diseases of special importance follows in separate paragraphs, as well as tabulations, indicating the amount of work done in the various laboratories.

Detailed tabulations of the work of all of the Army laboratories are available only for the months from February to June (inclusive) of the past year. Even for this period it is hardly profitable to present a detailed consolidated report of the number of various examinations carried out. It is of interest, however, in order to give some indication of the amount of work done in the laboratories of the camp base hospitals, to present the following table. In this a few of the more important types of examination are arbitrarily selected, and the average number of each performed per month in each of six of the camp base hospital laboratories is shown:

TABLE No. 154.—*Base hospital laboratory examination during the months February to June (inclusive), 1918.*

	Jackson.	Taylor.	Dodge.	Pike.	Travis.	Lewis.
Urinalyses	2,670	3,334	2,389	1,181	2,675	1,244
Blood counts	800	(1)	1,199	422	1,314	465
Malaria	619	....	40	183	108	....
Blood cultures	89	....	50	64	103	97
Sputum for tuberculosis	451	396	696	365	607	397
Urethral smears	228	....	860	....	....	353
Cultures for Klebs-Loeffler	13	....	4,681	4,017	....	789
Cultures for meningococcus	3,171	....	1,950	951	12,431	2,115
Typing of pneumococcus	103	42	38	119	731	67
Feces for ova	3,638	3,742	743	56	168	452
Wassermanns	1,422	407	623	276	583	398

[1] Report tabulated in a manner that does not permit calculation of this figure in all cases indicated.

The amount and nature of the laboratory work may also be gauged by the following complete tabulation of all the examinations made in Army laboratories in the United States for one month, March, 1918.

TABLE No. 155.—*Tabulation of laboratory examinations for the month of March, 1918 (57 laboratories).*

Examinations.	Number.	Examinations.	Number.
Urinalysis	58,877	Renal function	611
Blood counts	16,735	Wasserman, blood	14,689
Malaria	1,907	Wasserman, cerebrospinal fluid	160
Blood grouping	53	Complement fixation, gonococcus	127
Widals	70	Complement fixation, glanders	394
Gastric contents	801	Miscellaneous cultures	1,298
Feces, for ova	32,453	Water, bacteriological	832
Sputum, for tuberculosis	8,763	Milk, bacteriological	872
Darkfield examinations	714	Foods, bacteriological	77
Urethral smears	5,748	Autopsies	271
Miscellaneous smears	1,130	Histological examinations	492
Cerebrospinal fluid, cell counts	1,146	Gross specimens, preserved	11
Cerebrospinal fluid, colloidal gold	31	Special chemical examinations	47
Blood cultures	1,377	Miscellaneous examinations	2,887
Pneumococcus typing	2,607	Autogenous vaccines prepared	167
Nasopharyngeal cultures, Klebs Loeffler	41,313	Typhoid vaccinations given	9,275
Nasopharyngeal cultures, meningococcus	75,204	Smallpox vaccinations	2,796
Nasopharyngeal cultures, streptococcus	2,922	Serum treatments given	254
Pleural fluids	915	Rabies treatments	14
Urine cultures	1,943	Shick tests	1,215
Catheterized urine	33		
Urine, pneumococcus precipitin	141	Total examinations	293,430
Feces, cultures	4,475		

In addition to the work tabulated, certain special studies have been made at some of the camp laboratories. Among these may be mentioned the study of the bacteriology of the epidemic simulating influenza, a mosquito survey at Camp Custer, malarial surveys at Camps Dix and Jackson, and meningococcus surveys at Camps Jackson and Travis.

2. ROCKEFELLER INSTITUTE. (UNITED STATES ARMY AUXILIARY LABORATORY NO. 1.)

During the past year the Rockefeller Institute offered several courses of instruction for Army officers and enlisted men; has carried out certain investigations at the request of the Surgeon General; and has furnished certain sera and vaccines for the use of the Army.

At the war demonstration hospital at the Rockefeller Institute, which was constructed for this especial purpose, courses lasting two weeks were given twice a month, designed to teach the recent advances in war-wound surgery, and especially the art of applying the Carrel-Dakin treatment. This course has been given to 25 classes, attended by 436 medical officers of the Army under the direction of the surgical division. In addition special individual instruction has been given to 20 medical officers and 25 enlisted men.

In addition to this teaching, the laboratories of the war demonstration hospital have been engaged upon the investigations of particular subjects assigned by the Surgeon General, such as the action of other antiseptic drugs than sodium hypochlorite, the elucidation of the principles of the action of the antiseptics, and the application of the Carrel-Dakin method to the treatment of empyema.

Fundamental training in bacteriology and immunology has been provided in a course in bacteriology and serology, covering four weeks of intensive work, repeated once a month. These classes have been attended by 280 officers and 37 enlisted men.

Recently a course in clinical chemistry for medical diagnosis has been begun, each class continuing about six weeks. Seven officers and 52 enlisted men have taken this course.

For the purpose of instruction in the methods of pneumonia diagnosis and treatment and in the use of curative serum effective against the Type I pneumococcus, 27 medical officers have been sent to the Rockefeller Hospital and have served there as internes from periods of from six weeks to several months. This course has been con ducted under the direction of the division of internal medicine.

Four sera have been produced for the Army and Navy at the Rockefeller Institute in the following quantities:

	Liters.
Antimeningococcic serum	528
Antipneumococcic serum	286
Antidysenteric serum	44
Antigas-gangrene serum	150

In addition, 50,000 doses of antipneumococcus vaccine were prepared and used in the study of prophylactic vaccination against pneumonia at Camp Upton.

The institute has furnished assistance to the Army on several occasions in dealing with the problem of meningococcus carriers. Experiments have been conducted upon improved methods of treating these carriers and freeing them from meningococci. Ten such carriers from the Army have been treated in the Rockefeller Hospital and discharged as cured.

At Camp Funston studies upon the vaccination against epidemic meningitis were carried out by the Rockefeller Institute. A report of this study has already been made to the Surgeon General.

3. THE LABORATORY DIVISION OF THE AMERICAN EXPEDITIONARY FORCES.

In addition to the conduct of the work in camps in this country, the department of laboratories and of infectious diseases has cooperated with the chief of the division of laboratories of the American Expeditionary Forces. A statement concerning the laboratory work in France, and especially the very important investigations of trench fever, must await the arrival of the official report.

4. LABORATORY ACTIVITIES ASSOCIATED WITH THE MEDICAL SECTION—CHEMICAL WARFARE SERVICE.

Bacteriological and pathological investigations on the action of poisonous gases undertaken under the auspices of the Bureau of Mines over a year ago have been developed during this period into a division of the medical section of the chemical warfare service.

This work has been under the direction of several competent pathologists.

The studies have been conducted at several stations, including the American University and the Brady Laboratory of Yale University. The effects of many gases both in the gas chamber and under field conditions have been determined and more detailed histopathologic, bacteriologic, and serologic problems which may indicate methods of therapy are under investigation.

Eight different gases have been studied and reports of these investigations well illustrated with gross and microscopic drawings as well as several preliminary reports are rapidly approaching completion for publication.

5. PNEUMONIA AND EMPYEMA.

Pneumonia, in part secondary to measles, in part primary, has been the cause of about 65 per cent of the deaths in the Army in this country during the calendar year of 1917. Especial attention has therefore been directed to the study of this disease.

The isolation and typing of pneumococci from the sputum of patients with pneumonia either by the mouse or by Avery's method, or by both, has been made a routine procedure in the Army laboratories.

Following the institution of pneumococcus typing, the use of antipneumococcic serum in the pneumonias that are due to the Type I pneumococcus was commenced, and the use of this serum is now a routine measure for these pneumonias.

At Camp Upton almost half the Seventy-seventh Division was inoculated with a saline pneumococcus vaccine containing Types I, II, and III. During the 10 weeks that elapsed between the completion of this vaccination and the departure of the troops not a single instance of pneumonia of these three types occurred among the vaccinated men, while the incidence among the unvaccinated was higher than during the corresponding period preceding the vaccination. This has been deemed a sufficiently strong confirmation of Lister's findings in South Africa, to warrant an extension of the use of this prophylactic measure.

A commission was sent in February by the Surgeon General to Texas to study pneumonia from the clinical, bacteriological, and pathological aspects. Among other results the clinical and pathological characteristics of the pneumonia associated with the streptococcus hæmolyticus were analyzed by this commission. The pathology of this form of pneumonia for which the name "interstitial broncho-pneumonia" was chosen was described and the association of the hæmolytic streptococcus with this pathologic condition was demonstrated.

A technique has been elaborated for the isolation and identification of the streptococcus hæmolyticus from the sputum, nasopharynx, or other source. The recognition of the importance of this organism as an etiologic factor in one type of pneumonia, and that a very fatal one, is an important contribution of the past year.

In conjunction with the Surgical Division a commission was organized and sent to Camp Lee to study empyema, which has constituted such an important complication of pneumonia, especially in those pneumonias associated with the streptococcus. Metabolic studies were made by this commission indicating the necessity for a calorically high diet for these patients. Bacteriological and pathological studies were made in conjunction with the surgical investigations.

The apparent influence of measles in predisposing to infection with streptococcus hemolyticus, and the importance of this organism in inducing the complications of measles has been brought to light in studies from several of the Army laboratories. This has stimulated the making of streptococcus surveys by nasopharyngeal culture in the troops at some of the camps, to determine the incidence of this organism and its tendency to spread. It has also led to the devising and institution of methods for the isolation of patients with measles who have this organism in the nasopharynx, and for their separation from those with clean throats.

Investigations are at present in progress upon the nature of the virus of measles and upon measles prophylaxis, upon the efficiency of masking of cubicles for the prevention of respiratory infections and upon the proper pattern for an effective mask, upon the biology and the seasonal prevalence and virulence of the hemolytic streptococcus, and upon protective vaccination against pneumonia.

A board of medical officers was appointed by order of the Secretary of War, under date of May 20, 1918, for the purpose of making an investigation as to the nature, causes, prevention, and treatment of pneumonia and its complications in the various camps within the limitations of the United States, and to report from time to time to the Surgeon General of the Army. Three meetings were held previous to June 30.

One of these was in conference with a group of pediatricians, for the purpose of considering the management of measles and its sequelæ as they affect the military service.

This board has likewise reviewed the data thus far collected on the subject of pneumonia and its sequelæ, by various divisions of the Surgeon General's Office. It has considered methods for the earlier diagnosis and isolation of pneumonia in the camps and hospitals; the selection and detailing of small groups for the special study of pneumonia in these camps where it becomes especially prevalent; and the continuation of prophylactic vaccination against pneumonia.

6. ANTHRAX.

In March, 1918, a soldier developed anthrax on the neck, while on the transport en route to Europe. The lesion was in the shaving area. Examination of 15 shaving brushes from among the troops on this transport resulted in the finding of anthrax spores in all of the first six brushes examined.

Following this first instance, 14 men have been reported from overseas, with anthrax in the shaving area of the face or neck. All but three of them developed the condition while on the transport. Of the 15 patients, 5 died. Shaving brushes from the organizations of three of these men showed on bacteriological examination, the presence of anthrax spores.

In this country the first instance among the troops occurred at Camp Taylor in April, and up to June 30, 20 individuals in the Army in the United States had developed the condition, in every case the lesion being on the face or neck. Among these 20 patients there has been 1 fatality.

Upon receipt of the report from overseas, measures were taken to secure an examination of the shaving brush, soap, talcum powder, and other shaving accessories, from both the patient and others of his organization. Methods for the disinfection of shaving brushes were tested, that finally adopted being four hours' immersion in a formalin bath at 110° F. A circular calling attention to the necessity for the disinfection of shaving brushes, and outlining the adequate methods, was distributed to all commands. Subsequently, the entire manufacture of shaving brushes was investigated at the instance of this office, by the Public Health Service, and a list of manufacturers prepared, which included those who provided for adequate sterilization of their product. This list was distributed to all commands in order that unnecessary disinfection of brushes might be avoided.

In addition the Public Health Service of the United States has added an amendment (No. 6) to the interstate quarantine regulations of 1916, to prohibit the interstate transportation of shaving or lather brushes manufactured under insanitary conditions, and including anthrax among diseases regarded as contagious and infectious, for the purpose of interstate quarantine.

The statistics of the United States Public Health Service show an increase in the incidence of reported anthrax in the United States during the past few years. Thus, there were in 1915, 45 cases; in 1916, 106 cases; in 1917, 205 cases. It is not necessarily to be inferred, therefore, that the incidence of this condition is unduly high in the Army.

7. GAS GANGRENE.

In June, 1917, the discovery, at the Rockefeller Institute, of a true toxin for *B. welchii* (*perfringens*) was announced. This toxin upon injection into laboratory animals and horses, gave rise to a potent antitoxin. Several horses were placed under immunization at once, and in December the application of this serum to the treatment of gas gangrene was commenced in France. Before going to the British front the toxin, the antitoxin, and the protective power of the latter were demonstrated in London to the British Royal Army Medical Corps, and as a result large scale production of antitoxin was at once begun in England.

Subsequently it was decided by the laboratory council of the Central Medical Department, American Expeditionary Forces, that the gas gangrene serum might better be applied prophylactically, and in conjunction with tetanus antitoxin. Further, the work of French investigators had shown that gas gangrene is not caused exclusively by *B. welchii*, but that the Vibrion septique (*B. edematis maligni*) is a frequent complicating factor. This organism also produces a true toxin. It was therefore planned to produce as rapidly as possible a double serum, and ultimately a triple serum, tetanus-welch-septique, these combinations to replace at the earliest possible time the tetanus prophylactic injections now given to the wounded. Facilities for this production being lacking in France the immunization of tetanus immune horses with the toxins of *B. welchii* and Vibrion septique was initiated in the United States.

Quantity yields of the double serum (tetanus-welch) are already beginning to be secured (September, 1918), and in a short time the routine prophylactic antitetanus injections of wounded men will begin to be replaced by the double-serum prophylaxis. By the winter of 1918–19 the triple serum should be in production in large quantities. Experiments in prophylaxis have yielded striking results, and the outcome of the effect of the large scale application of the combined sera on the incidence of gas gangrene may be awaited with interest.

8. SECTION OF UROLOGY AND DERMATOLOGY.

In the experience of the European armies venereal diseases became so prevalent as to cause many men to become ineffective. With the idea of using all aids in the prevention of venereal diseases and in applying modern scientific methods to the cure of such cases as should occur, the Surgeon General requested a committee of men versed in the department of genitourinary diseases and syphilis to act as advisers to the chief of the division. One member of the committee remains on duty in the Surgeon General's office continually and the entire committee meets for a discussion of new phases of the work as they present themselves.

In addition to the Manual of Treatment, the committee has sent out at various times a number of circulars to medical officers in camps and posts giving advice, suggestions, and instruction in relation to various topics in connection with venereal diseases. Special inspection trips have been made by members of the committee from time to time as emergencies arose, and in the early summer every cantonment in the country was inspected by a member of the committee to learn from personal knowledge the actual conditions in the genitourinary and venereal disease sections of the cantonments.

The first task of the committee on its organization was to prepare a program of attack against venereal diseases, one member being placed in charge of the department of prevention and the department of treatment being undertaken by the committee as a whole. In order to attempt to standardize the treatment of venereal diseases the committee prepared a manual for the use of all medical officers describing diagnosis and treatment in a brief manner.

The next task of the committee was to select the personnel to take charge of the venereal work in the camps. The applications of men joining the medical service were looked over, the qualifications reviewed, and the men classified and graded according to experience and professional standing. In assigning the men to duty it was endeavored to send one experienced genitourinary man and one or more younger men as assistants to every base hospital and every cantonment. In the base hospitals the urological surgery, venereal diseases, dermatology, and syphilis were combined in one department under one chief.

As the number of men with adequate training was found to be insufficient for filling all the positions, it was found to be desirable to afford an opportunity for the postgraduate instruction of younger men who elected to work in the genitourinary section, in urology and venereal diseases, syphilis, and dermatology, and to that end postgraduate schools were established for medical officers at the postgraduate school in New York at Columbia University, in Boston in connection with the Harvard Medical School, and in St. Louis. Later on, these schools were discontinued and all postgraduate courses in urology and venereal diseases were instituted at Fort Oglethorpe, so that men entering the service could get their military training and instruction in urology at the same time.

While gonorrhea and syphilis form the large preponderance of the cases in the cantonments, there are always a fair number of cases requiring experts in urology and dermatology, and an important part of the duty of the committee consists in supplying medical officers trained to genitourinary and venereal work to the cantonments as the Army increases in size. The volume of work in this line increased so much that it was necessary to assign a personnel officer to this branch of the committee's activities.

Facilities were provided for the prompt application of venereal prophylaxis and punishment by court-martial for delinquents was insisted upon. The results are apparently satisfactory.

In order to facilitate the treatment of venereal diseases by the medical officers and the military instruction by the line officers, development battalions were formed in which patients are treated in venereal infirmaries.

9. VENEREAL DISEASE CONTROL.

An active propaganda for the prevention of venereal diseases in the Army was first initiated by this office in January, 1909. As a historical review it is interesting to note the following quotations from the reports of that period:

> The magnitude of the evil and the large loss from inefficiency in addition to humanitarian considerations have induced the military authorities of a number of military posts to take earnest steps to check the spread of these infections. Such steps have been the instruction of soldiers by lectures as to the danger of venereal diseases and the healthiness of continence; periodical inspections to detect and subject to medical observation and treatment those found diseased; the withdrawal of passes to be

absent from the post of such; and the issue of preventive medicines for local application to such as will not be restrained by considerations of morality or prudence from exposure. These antiseptic applications are given only upon the personal request of individuals. If such steps were taken universally throughout the Army and a campaign of education instituted which should reach each recruit from his admission to the service, it is believed that the evil record of the American Army might be greatly bettered.

This rather brief introduction of the campaign was followed by discussions of considerable length which appear in the Surgeon General's report of 1910. A partial quotation is as follows:

The venereal peril has come to outweigh in importance any other sanitary question which now confronts the Army, and neither our national optimism nor the Anglo-Saxon disposition to ignore a subject which is offensive to public prudery can longer excuse a frank and honest confrontation of the problem. There is no reason to think that these diseases are beyond the reach of preventive medicine any more than other contagious diseases and their immunity from restriction must be attributed to the public disinclination to discuss them and legislate concerning them. It is now believed by most sociologists as well as sanitarians that the evil being primarily a social one can only be reached by a propaganda of public discussion and education, and that education in sexual matters and in the danger of venereal diseases should begin with the young and be carried on by means of all the agencies of popular enlightenment. A number of State and municipal health authorities as well as private associations are now publishing and distributing literature on this subject. It is believed that the War Department can not do better than adopt this general attitude and many of these methods, including a philosophical indifference to criticism on the part of self-constituted censors of the public morals whose susceptibilities are offended by a public discussion of these questions.

This office, on the 25th of January, 1909, called the attention of medical officers throughout the Army by circular letter to the importance of making a vigorous and sustained effort to prevent the spread of these diseases.

Reports since the Spanish-American War show a steady and progressive increase in this class of disease, so that the admission rate, which was 84.59 per 1,000 in 1897, has now reached the enormous figure of 196.99 per 1,000. These figures are out of all proportion to those which obtain in the European armies, the rates for the latter being, according to the latest obtainable information:

British (at home 68.4)	75.8
Austro-Hungarian	54.2
French (at home 27.8)	34.8
Prussian	18.7
Bavarian	15.2

Among the measures which have been found most successful in other services in controlling this disease have been the following:

(1) The organization of soldiers' clubs, canteens, etc., where enlisted men can find amusement and recreation sufficiently attractive to keep them at home and away from vile resorts.

(2) The formation of temperance associations among the enlisted men, the association of intemperance and venereal indulgence being well understood.

(3) The early detection of all cases of venereal diseases by periodical physical examination of the men stripped.

(4) Keeping all cases of venereal disease under continuous observation and treatment until they are cured. For this purpose venereal registers are kept, and a case once on the books is never lost sight of until cured. Should a man be transferred while under treatment to another post or station, his venereal history goes with him.

(5) Instruction of the men by lectures and by informal advice whenever the opportunity offers as to the nature of venereal diseases, the extent of their prevalence among prostitutes, and the grave peril not only to those who contract them but to their families and posterity. They should also be taught that sexual intercourse is not necessary to good health and the highest degree of mental and physical vigor.

(6) Approved measures of personal prophylaxis of those who will, contrary to advice, expose themselves to venereal infection. All the principal European armies, with the exception of that of Great Britain, have officially authorized or directed the use of such prophylactic measures, and a considerable degree of success has attended their use. In some of the Austrian garrisons this system is said to have effected a

decrease of 62 per cent in the cases of venereal disease. In the German Army equally good results have been reported. The general procedure in all the armies is about the same, though there are slight differences in the details, especially in regard to the particular antiseptic employed.

The importance of personal cleanliness was emphasized and suggestions made for the providing of appropriate prophylactic preparations, where they would be accessible to men who desired to use them.

As the result of the campaign thus initiated and given wide publicity through the service by the discussion in the annual report of this office, as well as by correspondence with the chief surgeons of the departments, both in this country and the tropical islands where American troops were stationed, a great deal of interest was aroused among the medical officers of the entire Army. Excellent work was done by a large number of medical officers.

On January 18, 1911, the following letter was sent out from The Adjutant General's Office at the request of this office:

It is desired by this office to continue the study of means of reducing the very serious inefficiency from venereal diseases. For this purpose and in order to get information needed in the preparation of the annual report of this office for the calendar year 1910, it is requested that reports be called for from all post surgeons showing what steps are being taken at the posts for the instruction and protection of soldiers along the following lines:

(1) Instruction of the men by lectures, demonstrations, or printed circulars, by medical officers or company commanders regarding the dangers of illicit sexual intercourse and the advantages of sexual continence.

(2) For those who have not the moral stamina and self-control to observe continence, the necessity of using every precaution for personal cleanliness and also systematic disinfection after illicit sexual intercourse. All the information obtainable is desired as to the use of the "K" packet for the latter purpose.

(3) An expression of opinion is desired from post surgeons and commanding officers as to the efficacy of these measures, and suggestions are desired as to ways in which the prophylaxis of venereal diseases may be made more effective than at the present time.

During the early part of the campaign, department surgeons and individual post surgeons were allowed a great deal of latitude in the methods of prevention to be followed. The general plan was outlined, but the details for carrying out the plan was left to the preference of the individual officers concerned.

After several years the opinions gradually crystallized throughout the medical service that certain methods of prevention were advisable. Among other things, it was thought desirable that a law should be enacted by Congress stopping the pay of all men incapacitated for duty on account of venereal diseases. In addition to this, action by the War Department was considered desirable directing that a certain course of procedure be followed at every post and that men who failed to comply with the orders in regard to personal prophylaxis should be punished for failure to so comply.

The necessary laws were passed by Congress and were published to the Army in General Orders No. 31, War Department, 1912. The action of the War Department making certain measures compulsory and providing that men should be punished for failure to comply with these orders was published in General Orders No. 17, War Department, 1912.

It is enjoined upon all officers serving with troops to do their utmost to encourage healthful exercises and physical recreation and to supply opportunities for cleanly social and interesting mental occupations for the men under their command; to take advantage of favorable opportunities to point out, particularly to the younger men, the inevitable misery and disaster which follow upon intemperance and moral uncleanliness, and that venereal disease. which is almost sure to follow licentious living, is never a trivial affair. Although the chief obligation and responsibility for the instruction of soldiers in these matters rests upon company officers, the medical officers should cooperate by occasional lectures or other instruction upon the subject of sexual physiology and hygiene and the dangers of venereal infection.

Commanding officers will require that men who expose themselves to the danger of contracting venereal diseases shall at once upon their return to camp or garrison report to the hospital or dispensary for the application of such cleansing and prophylaxis as may be prescribed by the Surgeon General. Any soldier who fails to comply with such instructions shall be brought to trial by court-martial for neglect of duty.

Commanding officers will require a medical officer, accompanied by the company or detachment commander, to make a thorough physical inspection twice in each month of all the enlisted men (except married men of good character) of each organization belonging to or attached to the command. These inspections will be made at times not known beforehand to the men and preferably immediately after a formation. The dates on which the physical inspections of the various organizations are made will be noted on the monthly sanitary reports.

At these inspections a careful examination of the feet and footwear and of the condition of personal cleanliness of the men will be made, as well as careful observation for the detection of venereal diseases.

Cases of the latter will be promptly subjected to treatment, but not necessarily excused from duty unless, in the opinion of the surgeon, deemed desirable. They will be made of record in the medical reports in any case. A list of those diseased but doing duty will be kept both by the company or detachment commander and the surgeon, and the infected men will be required to report to a medical officer for systematic treatment until cured. While in the infectious stages the men should be confined strictly to the limits of the post. When a venereal case, whether or not on sick report, is transferred to another command, the surgeon will send a transfer slip giving a brief history of the case.

All instructions from the War Department prohibiting the publication in printed or other orders or instructions prescribing examinations having in view the detection of venereal diseases among enlisted men, heretofore issued, are recalled. (G. O. 17, 1912–1915, 426, A. G. O., as amended by par. III, G. O. 71, 1913–2092551, A. G. O.)

As a result of the active campaign which had been waged and of the two general orders mentioned, a great reduction in the prevalence of venereal diseases resulted.

During all these years, however, the medical authorities were greatly hampered on account of their inability to control the neighborhoods surrounding military posts. Also the difficulty of controlling alcoholic indulgence by the men while away from military posts made the problem much more difficult.

The campaign which had been initiated in 1909, and which had been so vigorously carried on in succeeding years by the military authorities, was continued during the year 1917.

These measures with the aid of all health authorities, both national as well as local, with the stoppage of the sale of all alcoholic liquors to men in uniform, with the excellent public-health supervision of the extra cantonment zones, and with the intensive training in which the men were engaged, all combined to render the control of venereal diseases among the enlisted men of the United States Army ideal. Chart 61 shows the rates for venereal diseases among the enlisted men of the United States Army.

With the expansion of this office in 1917 a special section of the division of laboratories and infectious diseases was established. This section was charged with the supervision and inauguration of prevention and control measures, and closely correlated with a section for the treatment of genito urinary and dermatological cases.

A special committee comprising the administrative personnel of these two sections was appointed to advise the officer in charge of the division. This committee prepared and distributed widely throughout the United States a program of attack on venereal diseases summarized under four headings:

A. Social measures to diminish sexual temptations.
   (1) Especially repression of prostitution and the liquor traffic.
   (2) The provision of proper social surroundings and recreation both within and without the military establishments.
B. Education of soldiers and civilians in regard to venereal diseases and the moral hazards related thereto.
   (1) For soldiers through official lectures, pamphlets, exhibits, motion pictures, and correlated educational work of the chaplains and representatives of religious and social agencies under the supervision of the Commission on Training Camp Activities.
   (2) For civilians through encouragement and assistance to professional, business, commercial, religious, men's and women's organizations and social-welfare associations.
C. Early treatment (or prophylactic measures) against venereal diseases.
   (1) Through treatment stations established in regimental infirmaries and in cities accessible to large numbers of troops.
   (2) Through follow-up measures adapted to individual cases to discourage subsequent exposures to infection.
D. Medical care of those infected.
   (1) Through hospitalization of all cases requiring such action for the best interests of the patient, for shortening of the noneffective period, and for the protection of other soldiers.
   (2) Dispensary treatment and follow-up supervision for those who do not require admission to or further detention in the hospital.

The importance was emphasized of correlating these four major lines of attack with the laboratory, sanitary inspection, hospital, and reconstruction divisions of the Medical Department on the one hand and on the other with the recreation, law enforcement, education, and clinic activities of the War Department Commission on Training Camp Activities and the United States Public Health Service.

The following paragraph was used to introduce a frank appeal for civilian cooperation:

> In its popular interpretation, social hygiene has been used as a phrase to refer inclusively to all efforts for protection of the population from prostitution and venereal disease. Prostitution in its various forms affords the chief opportunity for disseminating the venereal diseases and promoting sexual promiscuity. Neither the military nor the civil authorities have been able effectively to combat this medical social evil alone. The assembling of troops in the vicinity of civil communities has always introduced a difficult social problem on the one hand and on the other has attracted the promoters of organized vice, who have established the commercialized activities known to increase the supply and demand for prostitution. The civil authorities within whose jurisdiction these practices were carried on were inexperienced in dealing with the situation, and the military authorities had no legal power under which to take action.

The statement was made that the Army considered the problem of safeguarding the morals and health of its soldiers to comprise several groups of measures:

(1) For the protection of the drafted man while he is still at home, before being called to the colors, and while he is en route to his military station.

(2) For the protection of the soldier at all times while in the military service until final "muster out."

The work of the section during the past year has been devoted largely to planning and carrying out, directly or in cooperation with other departments or civilian agencies, measures applicable to each of these phases of the problem.

In addition to the administrative personnel of the section, an officer has been assigned to the War Department Commission on

Training Camp Activities to direct its law enforcement work for the repression of prostitution and the use of alcohol; the reduction of the number of carriers of infection through work with women and girls for their own protection and the protection of soldiers; and Federal assistance to States in provision for detention houses and reformatory facilities required for the care of civilian persons whose quarantine, isolation, or commitment to an institution is necessary for the protection of the armed forces of the United States from venereal diseases. Forty-five commissioned officers and an equal number of noncommissioned officers have been assigned as extra-cantonment zone officers for the promotion of this work under the direction of the chairman of the commission.

An officer has also been assigned for the direction of the social hygiene educational work of the commission, which supplements the company commanders' talks required by The Adjutant General and the medical instruction given by the regimental surgeons and other officers of the Medical Department. Ten commissioned officers and 47 noncommissioned officers have been assigned to this work.

An officer has been assigned to the direct supervision of the extra-cantonment early treatment (or prophylactic) stations in cities adjacent to military establishments or frequently visited by soldiers on liberty or furlough. Two commissioned officers and 150 noncommissioned officers and men have been detailed to this work.

In addition to the above, the section personnel has included a group of five officers for special assignment to epidemiological and sociological phases of venereal diseases control. Besides the various cooperative measures with States having bureaus of venereal diseases, arrangements were made with the States of Massachusetts, Kansas, and North Carolina for the assignment of officers from this group as chiefs of bureaus of venereal diseases, to demonstrate the relative values of special programs for the reduction of venereal diseases among civilians.

With the passage of the Army appropriation bill for 1918 establishing a division of venereal diseases in the bureau of the United States Public Health Service, the continuance of these demonstrations has been transferred to this division with the cooperation of the Army. The original Massachusetts demonstration has been enlarged to include the States comprising the Northeastern Department, i. e., Maine, New Hampshire, Vermont, Massachusetts, Connecticut, and Rhode Island, and the medical officer originally detailed to Massachusetts as medical-military adviser concerning venereal diseases will serve as the supervising director of the venereal disease bureaus of these six States, being detailed for special duty to the division of venereal diseases of the Public Health Service. Other officers have been assigned to this division of the service to direct educational activities being carried out in correlation with the program of the Army.

Another type of activity of the section is illustrated by the so-called Newport News or Hampton Roads demonstration. Newport News as a port of embarkation receives large bodies of troops from which all recognized cases of venereal infection have been removed prior to entraining for the port. The importance of protecting these troops from fresh infection can not be overestimated. With the approval of the Secretary of War, the Surgeon General, the commanding general, and the chairman of the Commission on Training Camp Activities have cooperated in carrying out with special thoroughness every measure thus far proved practicable in the protection of soldiers from venereal diseases and their prompt restoration to active service after infection.

Newport News presents such geographical, social, and industrial conditions as well as military and naval conditions that it was decided to make a demonstration of social hygiene measures for civil as well as military and naval protection. The offer of the American Social Hygiene Association to supplement as a volunteer agency the direct activities of the Government in this demonstration has been accepted. The section is furnishing commissioned and noncommissioned officers and enlisted men for the demonstration.

Since the infection of soldiers with venereal diseases occurs in civilian communities and not within the cantonments or other military establishments, the Medical Department has considered it justifiable to cooperate in every way with State and local civil authorities. Suggestions for State board of health regulations for the prevention of venereal diseases, approved by the Surgeons General of the Army, the Navy, and the Public Health Service, have been promulgated and in cooperation with the American Red Cross assistance has been given the United States Public Health Service in establishing Government clinics in 42 extra-cantonment cities. The need for Federal assistance to the States in extending diagnosis and treatment facilities to infected civilians during the national emergency and for perpetuating such facilities has been brought to the attention of Congress.

A considerable portion of the time of officers of the section has been devoted to explaining these needs through correspondence, interviews, and lectures given by invitation and to the preparation of data requested by Congress prior to the passage of the amendment to the 1918 Army appropriation bill with the appropriation carried by Chapter XV creating the Interdepartmental Social Hygiene Board, totals $4,100,000.

In providing for the Interdepartmental Social Hygiene Board, it was the purpose of Congress and the President to insure continued close cooperation of the several departments of the Government in correlating measures against venereal diseases with measures against prostitution, liquor, and the other evils ordinarily included under the term social hygiene. The personnel of this board comprises the Secretaries of War, Navy, and Treasury, and one member each from the commissioned personnel of the Medical Departments of the Army, Navy, and Public Health Service appointed by the three Secretaries, respectively.

Measures for the prevention of any human-carrier disease are limited without general compulsory immunization as in the case of smallpox or the active cooperation of informed individuals who constitute two classes—those already infected and those susceptible to infection. Since no practical methods of immunization against this group of diseases exist, special emphasis has been placed upon the development of educational measures. Five million copies of pamphlets and educational leaflets explaining the Government's social hygiene program and restating the essential parts of it in many different ways have been distributed, either directly by the Medical

Department or by the Commission on Training Camp Activities or other agencies with the approval of the Surgeon General.

Officers of the section have been detailed to the demonstration of several special methods of education through the use of these pamphlets, placards, lantern slides, and illustrated posters. Officers of the section have also been detailed to the development of special motion pictures. These officers in cooperation with others similarly detailed by the Army Medical Museum and representatives of the Commission on Training Camp Activities, the American Social Hygiene Association, the Young Women's Christian Association, other volunteer agencies, and individuals have thus far produced two films. One of these has been widely utilized in the educational program with the soldiers and has been increasingly in demand for promotion of the civilian campaign against venereal diseases which has been conducted simultaneously with that of the Army. The other film was intended primarily for use in civil communities to aid in the education of women and girls upon the importance of combating venereal diseases and maintaining moral standards. This film has likewise been increasingly in demand by military as well as civil authorities

The section activities thus briefly sketched relate primarily to activities in the United States. The medical officers in immediate charge of the treatment and control of venereal diseases with the expeditionary forces have been equally active in establishing essentially the same program although the emphasis on various factors has not been the same because of different conditions which they have had to meet. One officer of the section has been on duty during the year with the expeditionary forces.

The change in policy of the War Department from orders excluding all demonstrable cases of venereal diseases from enlistment in the Army to orders admitting all infected men whose condition is such that there is a reasonable hope that treatment will render them innocuous to others and available for even limited military service makes it difficult to compare without explanation the annual rates of previous years with the annual rate for the past year.

Chart 62, however, shows that even before the year 1917, the rates for venereal diseases at recruiting depots were always noticeably higher than for the other military posts in the United States. This shows that even then a large number of men were taken into the military service, either with active venereal diseases or in the incubation period when enlisted.

In an endeavor to still further reduce the damage to the efficiency of the Army caused by these diseases, the section has detailed officers to a study of the relations to the problem of colored troops and the civilian colored population. This is being done with the active cooperation of national and local organizations of colored people and societies interested in the advancement of the colored people. As a part of this special program, colored sergeants have been detailed in a series of camps to work with the colored troops and further efforts are being made to provide adequate recreation and treatment facilities.

Since recreation and wholesome entertainment are such important factors in counteracting the appeal to the soldier of sexual adventure during his leisure time, the section has assigned for temporary duty a number of noncommissioned officers and enlisted men to the war camp community service which is one of the organizations working under the supervision of the War Department Commission on Training Camp Activities.

The problem of venereal diseases has received unusual attention during the year, and every effort has been made to stimulate and follow up public interest in the prevalence of these diseases in the Army.

VI. Division of Internal Medicine.

1. GENERAL.

The war experience has convinced the allied nations of the necessity of expert revision of the diagnosis of tuberculosis in the Army. Thus the French have established several "centres du triage" and the Italians "diagnostic hospitals" for that purpose. This need was foreseen at an early date after the entrance of the United States into the war. Furthermore it seemed advisable to institute examinations in order to quiet the anxiety of the people which had been excited by reports which fortunately were found at a later time to be exaggerated, as to the alarming prevalence of tuberculosis in France and this course was recommended by the National Tuberculosis Association.

For these reasons it was decided in June, 1917, that the Army should be reexamined for tuberculosis. The work was done by physicians commissioned in the Medical Reserve Corps who had special qualifications as internists or tuberculosis specialists, of whom as many as 600 have been employed at one time or another at this task. For their guidance directions were drafted which are incorporated in Circular No. 20, S. G. O. The work which was delayed from various unavoidable causes was practically complete in March, 1918, so far as the forces in the United States were concerned, 1,200,990 men having been examined and 9,648 cases of tuberculosis having been recommended for discharge. Of the total 190,398 belonged to the mobile troops of the Regular Army with 1,444 rejections, a percentage of 0.758; 446,157 to the National Guard with 4,905 rejections, percentage 1.099; and 399,429 to the National Army with 2,597 rejections, percentage, 0.65.

With the increment of the draft call March 26, 1918, the primary examination after entrance into the military service was undertaken by the tuberculosis examiners so far as the lungs were concerned, and from that date has been carried on by them, 937,185 men having been examined and 5,331 rejected on account of tuberculosis up to June 30, 1918, a percentage of 0.567.

The work in tuberculosis was associated at an early date with that of reexamination for cardiovascular conditions and the two activities were combined to form the division of internal medicine. To this division were also assigned temporarily the phychiatric and orthopedic specialties and at a later time a section of gastroenterology was added to the tuberculosis and the cardiovascular sections.

It was soon found to be advantageous to institute a course of instruction in the diagnosis of lung conditions, especially tuberculosis, not only in order to increase the skill of the examiners, but also to observe their work and classify them according to their proficiency.

Instruction of this kind has been given uninterruptedly at the Army Medical School, Washington, D. C., and at the medical officers' training camps at Fort Oglethorpe, Ga.; Fort Riley, Kans., and, until its close, at Fort Benjamin Harrison, Ind. Similar instruction has also been imparted to the medical officers of various camps and hospitals in courses given by traveling instructors. In all about 500 medical officers have received this instruction. In addition to the examining boards, a tuberculosis specialist has been assigned to the base hospital of each of the division camps and to some of the general hospitals and in addition, a division specialist has been attached to the mobile troops of the greater number of the divisions.

The William Wirt Winchester Memorial Tuberculosis Hospital, New Haven, Conn., has been leased from the New Haven City Hospital for the period of the war for use as an Army tuberculosis hospital, being known as United States Army General Hospital No. 16. This hospital of 250 beds has been increased in capacity to 600 beds by the construction of temporary buildings of wood and is now in operation. At this hospital instruction is given to a class of medical officers from whom are to be selected the staffs for tuberculosis hospitals now under construction.

A sanatorium at Markleton, Pa., has been leased for temporary use as a tuberculosis hospital. This hospital has a capacity of 150 beds enlarged by the construction of three ward buildings to a capacity of 270 beds. This hospital is United States Army General Hospital No. 17. A hotel has also been temporarily leased at Waynesville, N. C., for use as a tuberculosis hospital. The buildings will accommodate 250 patients. Its capacity has been enlarged by the use of tentage to 500 beds. It is known as United States Army General Hospital No. 18.

A hospital of the capacity of 650 beds, of temporary wooden buildings has been constructed at Otisville, N. Y., upon the tract of land belonging to the City of New York and in part occupied by the New York City Municipal Sanatorium. It is United States Army General Hospital No. 8.

A hospital of the capacity of 1,000 beds is now under construction at Azalea near Asheville, N. C. The buildings are of a temporary character.

A hospital is also being built at Denver, Colo., with a capacity of 1,000 beds. The buildings will be of a permanent nature, the material used being hollow tile. The post of Whipple Barracks, near Prescott, Ariz., has been turned over to the Medical Department for use as a tuberculosis hospital. The buildings now standing will accommodate 200 patients and the capacity will be increased to 1,000 beds by the erection of temporary buildings. When all the construction contemplated shall have been finished 6,020 beds will be available for tuberculosis patients.

2. CARDIOVASCULAR SECTION.

One of the first activities of the cardiovascular section was the preparation of Circular 21, S. G. O., as a guide on the examination of heart and blood vessels. Prominent clinicians who were especially familiar with the diseases of the heart were commissioned from all parts of the country and were assigned in boards combined with the tuberculosis examiners, or separately, to make or supervise the cardiac examinations, of the Regular Army, officers' training camps, the National Guard, and the registrants for the National Army upon their arrival in camps. It has been found that groups of special cardiovascular examiners are needed permanently in these camps to which registrants are constantly being sent, while single cardiovascular examiners have been required at recruiting stations and barracks during the spring draft and at all camps or base hospitals. About 190 medical officers and contract surgeons have been employed for the work at various times. The number of cardiovascular examiners and specialists on duty in this country on June 17, was 111. During the examination of the first draft and the National Guard, 44 officers and 41 contract surgeons were assigned to this duty.

Percentages and causes of rejection during the first draft.—The methods of examination varied somewhat in different camps, so that the figures submitted by the examiners from different camps are not absolutely comparable, still the total figures for the examinations are so large that individual differences are obscured. It was found that during the examination of the registrants in camps, 2 to 5 per cent usually required a very careful examination of the cardiovascular system and were referred to a cardiovascular specialist for this purpose. The rejections for cardiac disease varied somewhat in the different camps. The results of the examination of 436,530 men, which have been carefully tabulated, show that the rejections for cardiac disease varied usually from 0.1 per cent to 1.4 per cent, but in one camp reached the very high figure of 4.6 per cent. Including this camp, the rejection of the total strength was 0.94 per cent. Exclusive of this camp, the percentage of rejection was 0.5 per cent for all camps. The percentage of rejections at the National Army camps was slightly higher than that at the National Guard camps—0.63 per cent for the National Army and 0.47 per cent for the National Guard.

The causes for rejection and the relative frequency with which the different forms of organic heart lesion were found were strikingly similar in the different camps. The accompanying table shows the causes for rejection of 4,622 instances of heart disease and cardiac disturbances.

Summary of causes of rejection by cardiovascular boards in National Army and National Guard.

	Number rejected.	Mitral.		Aortic.		Tachycardia.		Hyperthyroid.		Myocarditis.	
		Number.	Per cent.	Number.	Per cent.	Number.	Per cent.	Number.	Per cent.	Number.	Per cent.
National Army........	2,681	1,552	58	326	12	140	5	159	6	244	9
National Guard........	1,941	1,088	56	301	15	54	3	258	13	180	9
Total............	4,622	2,640	57	627	14	194	4	417	10	424	9

During the second draft, beginning May 1, 1918, reports from 305,864 examinations have so far been received. The rejections for organic heart disease are practically the same as during the last draft, being about 0.5 per cent. The total rejections, including functional cases, however, is higher, being 1.13 per cent.

In addition to the cardiovascular examiners, one officer who had had special training in the examination and care of cases of heart disease has been assigned to the medical service of each cantonment hospital. To these officers men who have broken down during their training with cardiac symptoms have been referred, and in some camps methods have been established for retraining and systematic exercise for many of these soldiers who are suffering from such functional disturbances as "irritable heart."

Instruction.—A school of instruction in the methods of examination of the cardiovascular system was first started at the hospital of the Rockefeller Institute. During the late summer and autumn 18 officers of the Medical Reserve Corps received instruction in this course. Later, in conjunction with the tuberculosis division, courses of instruction in the physical diagnosis of the chest were organized at the medical officers' training camps at Camp Greenleaf and Fort Riley.

During June of 1918 a more advanced course of instruction in cardiovascular diseases has been established at United States Army General Hospital No. 9, Lakewood, N. J. A small group of student officers are given advanced instruction in preparation for work as cardiovascular specialists on examining boards and in base hospitals. Still another method for the instruction of Medical Reserve officers has been made available through the cooperation of the British Government, and during the winter and spring 20 officers have been assigned for instruction at the British Heart Hospital, Colchester, England.

Instruction has been given not only in cardiovascular diseases but in other subjects. It was early recognized that lobar pneumonia would prevail throughout the camps during the winter, and preparations were therefore made to furnish to each base hospital an experienced clinician who was thoroughly trained in the newer methods of laboratory diagnosis and serum treatment of lobar pneumonia. A few such men were immediately available and were detailed for work in those base hospitals where pneumonia was most prevalent, but other officers who were specially selected for this service required further training, and to this end a course of instruction by Dr. Rufus I. Cole and Capt. Dochez was instituted at the hospital of the Rockefeller Institute under the direction of Maj. Simon Flexner. Twenty-six officers have been trained at the Rockefeller Hospital. Recently this special school of instruction has been transferred to Camp Jackson, where officers are now being assigned for an advanced course.

Previously a small number of Medical Reserve Corps officers had been assigned to Camp Jackson for instruction in meningitis. The course has now been combined with the instruction in pneumonia, and to it has been added instruction in general medicine. Officers selected for the purpose have been assigned to duty at this hospital to assist the chief of medical service in the instruction of these student officers. Similar courses of instruction in general medicine are now being given to medical officers assigned as assistants to the chief of medical service at the base hospitals at Camp Devens, Camp Meade, Camp Sherman, and Camp Custer.

3. MEDICAL PERSONNEL OF BASE HOSPITALS.

During the organization of the base hospitals in this country the division of internal medicine was requested to select the chiefs of medical service for these hospitals. Later the assignment of all officers for duty on the medical services of base hospitals and United States Army general hospitals in this country, as well as on the medical services of the base hospitals and evacuation hospitals for over-seas duty, was referred to the division of internal medicine. The chiefs of medical service have been selected from among the most prominent clinicians in the country, while every effort has been made to assign to the medical services as assistants officers who have had hospital experience and some training in internal medicine. There have now been assigned by the division of internal medicine 67 officers as chiefs of medical services and approximately 1,000 assistants on the medical services of base, general, and United States Army hospitals in the United States. In addition to this, 36 officers have been assigned as chiefs of medical service of overseas base hospitals, and 22 officers as chiefs of medical services of evacuation hospitals. As assistants to the chief of medical services, 153 officers have been assigned to these hospitals.

By means of questionnaires sent from the hospital division to all hospitals in this country, all officers retained by the division of internal medicine have been classified according to the estimate of their qualifications rendered by the commanding officers and chiefs of medical service. By this means it is possible to release all men unfitted for hospital work for other services and to keep the personnel of the base hospital on a high level of efficiency. Finally, with a view to improving the medical services, each chief of medical service was ordered to visit during February and March three other base hospitals.

4. SPECIAL SERVICES, ETC.

During the period in which the epidemic diseases were prevalent, three mobile medical units were organized, each composed of three officers selected for their knowledge of infectious diseases. These units were moved from one hospital to another to assist in the care of cases of infectious disease. Other groups of selected officers have been assigned for the clinical work with a commission to study pneumonia at the base hospital, San Antonio, and at the base hospital, Camp Cody, with a commission for the study of empyema at the base hospital, Camp Lee.

In order to obtain data regarding the incidence of different types of pneumonia, the mortality and the results of specific treatment of this disease, a questionnaire was sent in conjunction with the laboratory division to the United States base and general hospitals in this country.

5. SPECIAL HOSPITALS.

Three general hospitals have been designated as those to which cases of heart disease are to be sent for special treatment. These three hospitals are United States Army General Hospital No. 9, Lakewood, N. J.; base hospital, Fort Des Moines, Iowa; and United States Army General Hospital No. 6, Fort McPherson, Ga. At General

Hospital No. 9 at least 100 beds have been set aside for the cardiac service. Every effort has been made to equip this service, not only for the routine care of cardiac patients, but for the special investigation of the condition known as the "effort syndrome" or "irritable heart." Officers have been selected for this work who are trained investigators and clinicians and who are believed to be the best men in the country for this particular work. The hospital has been equipped with a heart station and electrocardiograph, as well as some special physiological apparatus which will be required for this work. Request has likewise been made for an electrocardiograph and heart station at Fort Des Moines and, should the need warrant it, a heart station will be requested for United States Army General Hospital No. 6.

A section on gastroenterology was created as a part of the division of internal medicine in October, 1917, the special object of which was to furnish an officer especially trained in gastroenterology for service at each of the base hospitals. Practically all the base hospitals have thus been provided.

It is impossible to close this report without calling attention to the valuable and untiring services which were so freely given by the late Maj. Theodore C. Janeway in helping to organize and define the policies of the work of this division. His untimely death deprived this division, as well as the entire country, of an officer of mature and well-balanced judgment and of great skill.

VII. Division of General Surgery.

The division of general surgery was organized to classify the surgeons of the Medical Reserve Corps according to their professional qualifications, to provide schools for the training of men less proficient, to standardize surgery and equipment, to inspect the surgical staffs of hospitals, to maintain and increase surgical efficiency by the organization of surgical teams and the investigation and consultation of special surgical problems as they arise.

1. Surgical Equipment Board.

This board was formed to investigate and examine surgical equipment and appliances and to standardize them in regard to type quality, and quantity, according to the needs of the surgical service.

Owing to the war our imports of high-grade surgical instruments from other countries have been curtailed, it was necessary to draw upon our own manufacturing resources to meet the urgent demand for instruments. In order to secure them in sufficient number types were adopted that were simple and capable of being produced in large quantities in the quickest time. Although not always the most suitable they were used until they could be replaced by others more desirable.

The standardization of surgical instruments and appliances has done much to promote rapid equipment of our hospitals and the efficiency of the service.

In the early stages of production numerous cases of faulty surgical equipment was discovered as result of the use of inferior materials and poor workmanship in the endeavor to secure quantity production to meet the emergency. Since the first urgent demands have been met, instruments of better material and workmanship have been substituted for those found faulty or of unsuitable design.

The gauze situation, like that of instruments, became very acute in the early months of the war. After numerous experiments a knitted gauze was adopted as standard. This type of gauze can be used several hundred times and is now being supplied to all hospitals in the country of 100 beds or over. A special laundry unit under the supervision of a sanitary officer has been arranged for at each base hospital for the reclamation of the used gauze. It is hoped in the near future to install portable laundry units in the overseas and evacuation hospitals.

In adopting a portable type of oxygen-gas apparatus it was necessary to take into consideration its portability and adaptability to the conditions encountered overseas. Several types have been adopted as standard and are now being issued as rapidly as possible.

From the results of the experiments carried on by the Rockefeller Institute of Medical Research of New York and the surgical and medical staffs of the base hospitals the value of Dakin's solution in certain infections has been established. Owing to a widespread streptococcic invasion in this country it was necessary to supply a large number of the Carrel-Dakin apparatus to the base hospitals. The supply is adequate both for this country and overseas. All questions as to the proper type of apparatus for administering or manufacturing Dakin's solution have been referred to the Rockefeller Institute for their recommendation and the methods employed at this time are satisfactory.

As an aid to the conservation of transportation space a wheeled stretcher carrier, equipped with a metal litter, designed to fit any type of standard field litter, available for either hospital or field service and as an emergency operating table, was devised and developed in the office of the Surgeon General.

Provisions have been made to increase the sterilization facilities at base hospitals which have not proven adequate. Where the operating pavilions are to be enlarged, an additional sterilization unit will be installed, that pus and clean services may be effectively separated. Active cooperation has been encouraged in the hospitals between the chief of laboratory service and surgical service.

An operating table more durable than the one now in use has been recommended for immediate issue.

Drugs for local anaesthesia are now supplied where needed although during the recent epidemic of empyemia they were somewhat unavailable.

Orthopedic apparatus and appliances are being gradually standardized.

A more efficient lighting unit for operating rooms is being installed where required.

An increased supply of Monorief dressing sets is being provided to facilitate ward work. The large number of empyema and other primarily infected cases makes it essential to facilitate this daily labor. A reserve supply of all base hospital surgical instrument equipment has been recommended.

Where experience has proven the inadequacy of any particular instrument for the type of work that develops in any service, suitable substitutions have been made.

Some few shipments of foreign-made instruments, especially hemostats, have been found on inspection to be below the standard. This deficiency is in process of correction.

Needles are now available in abundance, and for spinal anaesthesia a flexible, nickeloid type has been substituted.

The mobile operating unit now completed and ready for service, has been fully equipped with specially constructed motorized sterilizers, X-ray outfits, and surgical instruments, with a suitable reserve supply for all emergencies.

Many other changes, additions and substitutions of varying importance have been recommended, and it is believed that in so far as is practical the foundation for standardization and adequate provision for a supply of surgical instruments and equipment to meet the needs of the service has been successfully established by the supply division.

2. MAINTENANCE OF SURGICAL EFFICIENCY.

This department has charge of the inauguration and supervision of classes for intensive instruction in war surgery and fractures, the treatment of infected wounds by the Carrel-Dakin method, the instruction in the administration of anaesthetics, the supervision of the character and efficiency of the surgical work done throughout the Army, the inspection of the surgical staff at hospitals and the investigation and consultation with regard to special surgical problems as they arise.

The question of the instruction of medical officers was a complicated one, but was handled with due deliberation after procuring data by questionnaires and personal visits to the various cantonment hospital multiple inter-office consultations. Various schools in New York, Boston, Philadelphia, Chicago, Pittsburgh, Cleveland, New Orleans, and Rochester (Minn.), have been detailed to give intensive training and clinical instruction to the medical officers. In the cantonment hospitals every possible aid to the teaching of surgery was utilized.

The educational phases of the work have had to do with the problem of bringing to the surgical staffs of the hospitals the latest information upon war surgery, and such other instruction as would fit the members of the surgical service for the proper care of patients in hospitals. Outlines of lectures have been prepared for instruction in hospitals; abstracts of the literature of war surgery up to the present have been furnished the surgical staffs; a monthly abstract of current war surgery is being published; classes already formed in various surgical centers have been supervised and other classes added; moving pictures and lantern slides have been produced and sent to the hospitals.

The class work has consisted of 11 classes dealing with war surgery and fractures. These classes last for approximately three weeks and have sent to them from various parts of the United States those members of the service whom it is felt would be benefited by an intensive course in the treatment of war injuries. These men on their return to the camps instruct those who have not attended the course.

In addition to this, a special course in the Carrel treatment of wounds, inaugurated some months ago, has been maintained at the Rockefeller Institute.

These lectures outlined have had to do with war surgery, and have been sent as a part of the abstract of war surgery (noted above) to the various cantonments for the use of those who lecture on surgery and who will be called upon to instruct the other members of the staff.

A series of 200 lantern slides dealing with war surgery and used to illustrate and emphasize the lectures have been prepared. For a similar purpose, a moving picture upon the treatment of wounds, and a second upon the treatment of burns have been produced and are on a circuit going to the various camps.

The abstract of war surgery, in preparation of which Maj. Kanavel was assisted by Maj. Seelig, is a volume of 300 mimeographed pages, and brings the war literature up to date. It has been sent to the camps, evacuation hospital groups, and others who will come in direct contact with war surgery.

The monthly Review of War Surgery and Medicine was inaugurated as a part of this educational program, but is now under the supervision of Maj. Seelig, who has taken entire charge of collecting material and publishing it. It is a monthly magazine of 64 pages containing reviews of war surgery.

About one-half of the hospitals and the training camps at Fort Riley and Fort Oglethorpe have been visited, where the inspecting officer has had conferences with the chiefs of the surgical services and the personnel. The cases in the wards have been observed, and suggestions made as to treatment and care of the patients. During these visits, special attention was paid to the surgical technique so that the division of surgery is constantly in touch with the character of the work being done, and in a position to place its officers properly, and to assure to the patients proper surgical attention.

The procuring of monthly reports from all hospitals has also aided in maintaining professional efficiency. A monthly report is required from each hospital covering the details of surgical operations, supplemented by a special report as to deaths and clean wounds that become infected. A study of these reports and the action upon them by Maj. Kanavel has served to keep the office in touch constantly with the character of the work being done in all hospitals, and has permitted us to follow up in detail patent errors in service or every death that has occurred. Through the reports he is able to check up upon the technique in the various hospitals, and in those cases in which infection of wounds or death has ensued, we have been able to place the responsibility and institute the changes necessary to maintain efficient service.

Attention to special surgical problems has also been under Maj. Kanavel's supervision.

During the months of December, January, and February, a considerable number of cases of pneumonia were reported from all the camps in the South. Accompanying this epidemic of pneumonia, so called, a large number of empyemas began to be reported. During an inspection trip through the different camps it was recognized that this epidemic of pneumonia with empyema accompanying it constituted a type of general septicemia with tendency to localization in the lungs and pleura; that the invading organism was in the greater proportion of cases a streptococcus, generally of the hæmolytic type. At all of the camps much work has been done in attempting to determine the nature of the infection. The mortality varied from 40 to 70 per cent in those cases in which a large amount of fluid developed in the pleura cavity. The method of treatment in the early stage of the epidemic had been universally drainage by removal of one of the ribs, generally in the mid-axillary line, but in some of the camps repeated aspirations had been attempted. In some of the camps the number of cases showing empyema, so called, had been considerably over one hundred.

Owing to the gravity of the situation, study of the subject was begun. In addition to committees from the Surgeon General's Office, through the commanding officer of each of the base hospitals, local teams were formed in each hospital from the attached personnel, consisting of a surgeon, an internist, and a bacteriologist, to study the local conditions. All this information was collected in the Surgeon General's Office and disseminated to the various camps.

As the spring advanced, the epidemic spread to the North and Camps Dodge, Taylor, and Custer became invaded. At Camp Dodge, a study was made of the pathology of this condition. As a result of the investigations, the pathological nature of the disease was established. The commission at Camp Lee soon established the wiser procedure in streptococcus infections and insisted on conservative treatment until the acute pneumonic process had subsided. During this period aspiration was undertaken if the respirations were seriously embarrassed. As soon as the resistance of the patient had been raised somewhat, and the acute pneumonic process had subsided, drainage between the ribs was instituted by means of a thrutter valve tube. This being soon withdrawn, it was found that these cases could be healed within three weeks after drainage was instituted. At the Rockefeller Institute under Maj. Stewart, early operation followed by the installation of Dakin's solution, was followed by considerable primary mortality, owing to the early operative procedure, but the important fact was established that in 80 per cent of the cases in from a week to ten days a pleural cavity could be rendered sterile and the wound sutured without subsequent drainage. The general nature of the treatment as instituted at Camp Lee had already been arrived at in a great many of the camps, notably, Taylor, Pike, Lewis, etc., so that the principle of conservative treatment at the early stages became firmly established.

At this time the subject of the treatment of chronic cases was begun by the commission and others, and the Surgeon General's office began to accumulate these patients in separate centers for intensive study.

3. SUMMARY OF REPORT ON REPLIES TO QUESTIONNAIRE ON EMPYEMA.

A. MORTALITY.

The numerous cases of empyema which have occurred in many of the camps during the past winter have presented features so unusual and oftentimes so puzzling that it is the almost unanimous opinion of those who have seen many of them that the particular complex of symptoms and pathological findings presented by them is new. Medical officers of wide experience both in civilian and military life state unreservedly that they have never before met with anything which corresponds with the recent type of empyema or compares with it in severity.

The average mortality based on replies from the 25 camps which gave their results has been 30.2 per cent. But this mortality, as high as it is, does not begin to represent the remarkably high mortality which has occurred in some of those camps which have had a large number of cases. For example, at Camp Funston, in 85 cases of empyema, the mortality has been as high as 84 per cent. Again, at Camp Greene, in 92 cases of empyema, it has been 53.2 per cent; at Doniphan it has been 57 per cent; and at Wheeler, 65 per cent. These high figures are to be contrasted with the records of no mortality at Camps McClellan and Wadsworth, where in each instance relatively few cases of empyema developed, as, for example, only 6 cases at McClellan and 2 cases at Wadsworth.

Certain factors have apparently had a remarkable influence in producing this high mortality. Chief of these undoubtedly has been the type of organism concerned. It is practically the universal opinion that those cases of empyema associated with the prevailing strain of hemolytic streptococcus have had a much higher mortality than those associated with the pneumococcus. This fact is strikingly shown in the report from Camp Funston, as follows:

Cases of empyema secondary to primary lobar pneumonia	47
Deaths from these cases	32
Mortality (per cent)	68
Cases of empyema secondary to measles-pneumonia	38
Deaths from these cases	36
Mortality (per cent)	95

In this series, 95 per cent of the cases of measles-pneumonia were found to be associated with a streptococcus (chiefly hemolytic), and in 60 per cent of the cases of primary lobar pneumonia, a streptococcus (again chiefly hemolytic) was found. This relationship between organism and mortality has also been borne out at Camp Sheridan, where it is reported only pneumococci were found in the pleural fluids and the mortality has been only 13 per cent. At McClellan, where there was no mortality, streptococci were found in only two of the six cases in which positive cultures were obtained. At Wadsworth, where there was also no mortality, the streptococcus was found in one case and the pneumococcus in the other of the two cases reported.

Another factor of great importance has been the occurrence of many of these cases of empyema secondary to a pneumonic process associated with measles, as will be seen in the report from Camp Funston given below. The influence of the measles in increasing the mortality is strikingly shown also in the following report from Camp Greene:

	Per cent.
(*a*) Empyema following pneumonia without measles:	
Total cases, 35; deaths, 18; mortality	51.4
(*b*) Empyema following pneumonia (lobar or broncho) after measles:	
Total cases, 14; deaths, 10; mortality	71.4
(*c*) Empyema after measles without pneumonia:	
Total cases, 29; deaths, 18; mortality	62.0
(*d*) Empyema without measles or pneumonia:	
Total cases, 14; deaths, 4; mortality	28.5

Again, in the reply from Camp Gordon the statement is made that 75 per cent of the fatal cases of empyema were associated with a post-measles pneumonic process; and of the 10 deaths at Shelby, 8 were cases which developed after measles.

Possible explanations of the striking differences in mortality reported from various camps in the empyema cases are to be found, (1) in the fact that there has been a marked disagreement concerning what cases should be considered as empyema, and (2) in the methods of treatment employed.

Owing to the fact that the exudate most commonly found is a slightly turbid serofibrinous fluid, with pus demonstrable only microscopically, in some of the camps only those cases have been considered as empyema which yielded frank macroscopic pus. In general, those camps which reported the lowest mortality have regarded as cases of empyema only those in which the exudate has been frank pus; and conversely the highest mortality figures have come from those camps in which all cases showing even microscopic pus in the pleural exudates have been considered as cases of empyema.

The relationship of methods of treatment to the mortality will be considered in detail in section 5 below.

B. PATHOLOGY AND BACTERIOLOGY.

The most striking feature about the pathological picture has been, in general, the multiplicity of the lesions and the pronounced evidence of a systemic infection. In those cases associated with empyema the pleural lesion has often been insignificant compared with findings elsewhere in the body. The whole process has been distinctly atypical when compared with the usual empyema, secondary to lobar pneumonia, with which everyone is familiar. There has been evident a well-marked tendency to involve serous membranes in general, which has been particularly manifested by rather frequent affection of the pericardium and the peritoneum, and less frequent involvement of the endocardium and synovial membranes. This tendency has been so pronounced that in the reports from many of the camps it has been distinctly stated that the empyema has been merely one manifestation of a "polyserositis." Other cases have been admitted directly into the pneumonia wards with pulmonary symptoms and physical signs suggestive of broncho-pneumonia. Other cases have followed tonsillitis or pharyngitis. In the fatal cases the patients presented the picture of a severe infection. Often the physical signs in the chest were slight or obscured and the final accumulation of fluid was very rapid. At necropsy a general septic lymphadenitis was found. Usually the spleen was not enlarged and did not present the picture seen in the spleen of a lobar pneumonia due to pneumococcal infection. The various serous membranes were involved to a varying extent, the secondary lesion being now in one membrane such as the peritoneum, and again in the pericardium. Four cases of vegetative endocarditis were found, one of which had progressed to the ulcerative stage. Broncho-pneumonia of some degree was present in all the fatal cases of empyema. The extent of the infection outside of the pleura was so great as to preclude the possibility of recovery either with or without operation. Streptococci were usually recovered from the heart's blood postmortem.

The characteristics of the exudate have varied greatly in different cases. The exudate most often has been serofibrinous in nature, odorless, and with a slight turbidity, due chiefly to the presence of relatively few polymorphonuclear leucocytes. It has usually contained micro-organisms (chiefly streptococci) in such large quantities that they could be demonstrated in smears in abundance.

When distinct pus has been present it has usually been in relatively small localized abscesses. The amount of the exudate has been subject to very wide variation.

In many cases, owing to the extensive development of fibrinous adhesions, there has been a marked tendency of the exudate to become sacculated with the formation of multiple pockets. These pockets have been particularly frequent in the interlobar fissures and under the sternum beneath the anterior flap of the lung. Camp Sevier has reported that in all the autopsies in which empyema was present (five cases) substernal pockets of pus were found. Camps Greene, Lee, Shelby, Sherman, Travis, and Upton all state that substernal pus pockets have been observed frequently.

The replies from different camps indicate rather a wide divergence of opinion as to the essential pathology of the lung conditions found n the majority of the cases of empyema. In general some sort of a pneumonic process has been present, described usually as either a obar or broncho pneumonia. An initial broncho-pneumonic process by extension frequently became so massive that it took on a lobar distribution, or even involved the whole lung. Abscesses of the lung have been rather frequently observed. Collections of pus have occasionally been found extending into the lung from the periphery as f secondary to the pleuritis. In general, however, it would seem hat, at least in the majority of cases, the essential pulmonic lesion has been an inflammatory process involving the finer divisions of he bronchi and the tissue immediately surrounding them.

The right side has been affected slightly more often than the left with both the pneumonic process as well as the empyema. Bilateral nvolvement has been frequent. Figures given by 14 camps show hat 8.7 per cent of all cases of empyema were bilateral, and that the pneumonic process was bilateral in 13.5 per cent of all cases of mpyema.

The statistical relationship of empyema to pneumonia is inter-sting. From figures available from many camps it is found that 9.7 per cent of all cases of pneumonia developed empyema. But ven more interesting is the fact that whereas 14.5 per cent of all iagnosed cases of lobar pneumonia were associated with empyema, s many as 21.1 per cent of all cases of pneumonia following measles eveloped empyema.

Figures from 17 camps indicate that 9.2 per cent of all cases of mpyema were associated with a pericarditis. Peritonitis has been relatively frequent concomitant lesion. It has occurred in 6.4 per cent of all cases. Endocarditis and arthritis have been encountered ccasionally. Sinus involvement and meningitis have been ex-remely rare.

The bacteriological findings have shown considerable variation both in the examination of the various exudates and in the culture rom the blood.

In 19 of the 27 camps from which replies were received a hemolytic streptococcus has been found much more frequently than any other organism. For example, at Custer, with one exception (pneumococcus, Type IV), all the cases have shown a hemolytic streptococcus. At Dodge a similar organism has been found in all but two cases. At Lee it is stated to have been found practically without exception, and at Kearney it was present in 80 per cent of the cases. These findings, however, are to be contrasted with those at Sevier, where no streptococci were found, but pneumococci were present as follows:

	Cases.
Type 1	2
Type 2	1
Type 3	0
Type 4	39
Sterile	9

At Wheeler also the pneumococcus was found much more often as follows:

	Cases
Pneumococcus	85
Streptococcus	9
Staphylococcus	4
Negative	25

At Beauregard the pneumococcus was found in 100 per cent of the cases, of which 52 per cent were Type IV and 40 per cent Type I Other camps reporting chiefly pneumococcus infections are Hancock Jackson, Logan, Sheridan, and Travis.

Many cases presented a mixed infection of both streptococci and pneumococci. Other organisms reported to have been found occasionally are staphylococcus, bacillus influenzae, and bacillus col communis.

The blood cultures, for the most part, have been sterile, but in the great majority of cases, when an organism has been obtained, it has been a hemolytic streptococcus. Repeated cultures have often been necessary in order to obtain a growth, and as a rule the moribund cases have yielded a positive culture. Occasionally the pneumococcus has been recovered from the blood.

C. PRECEDENT DISEASE AND CLINICAL COURSE.

Only slight information about the clinical features of the conditio is presented in the replies; but certain facts stand out prominentl and are deserving of emphasis. These concern (1) the question o the relationship to a precedent measles; (2) the incidence of an antecedent infection of the mouth and respiratory tract; (3) the fulminan character of some of the cases.

Already in section 1 mention has been made of the frequency o empyema after measles in some of the camps and of the apparen influence which the association with measles has had upon the mor tality. It is impossible to get accurate statistical data on the relationship of measles to the development of empyema, because mos of the replies from the camps do not state the number of cases respectively, of measles and empyema. Probably, however, measle has been an antecedent in only a minority of the cases. Custer' report states specifically that measles has preceded the empyema i less than half of the cases and groups the apparent primary lesions in its series as follows:

	Cases.
Lobar pneumonia	4
Bronchial pneumonia	16
Admitted with empyema	4
Following measles	18
Following bronchitis	6

At Doniphan there were 230 cases of lobar pneumonia, with 23 cases of empyema and only 1 case of empyema after 6 cases of bronchopneumonia following post measles. At Lee over 50 per cent of the empyemas were considered primary without an antecedent measles. In a few camps, notably at Custer, it has been observed that many of the cases of empyema were associated with a tonsilitis or pharyngitis, and bronchitis is mentioned frequently as a precursor of the empyema.

The rapid development of the condition after a sudden onset has been sufficiently frequent to cause comment in a number of the camps. Occasionally within 24 or 48 hours after an onset with chill a pleural cavity has been found to be nearly filled with exudate.

D. DIAGNOSIS.

In general the chief reliance in the recognition of empyema has been placed upon the standard method of physical diagnosis and paracentesis. In many of the camps, however, in addition to these methods, the X-ray has been found to be of great value.

E. TREATMENT.

The high mortality in all the camps bears evidence of the generally unsatisfactory results of the treatment of the condition. On the basis of the usual experience with collections of purulent fluid in the pleural cavity, it apparently seems rational at first in all the camps to institute free drainage by opening the chest; but later as experience became greater with this unusual type of empyema, considerable doubt, in some of the camps at least, was cast upon the efficiency of instituting drainage through a permanent opening in all cases, particularly in early cases when the patient seemed to be overwhelmed with the toxemia. The report from Custer states that in some of the cases in which the fluid was small in amount and the patients were in bad condition only aspiration was performed without operation. At Camp Funston it was found by experience that early repeated aspirations are safer than immediate operation. The remarkable reduction in this camp after January 1 compared with the previous mortality is perhaps to some extent ascribable to this procedure. At both Gordon and Grant the conclusion has been reached that early operation is inadvisable. At the latter camp the serofebrinous fluid is removed by repeated aspirations, and the mortality has been only 15 per cent. At Greene an immediate operation is considered advisable, except in those cases in which the pneumonia is still in an active stage and is considered the chief cause of the symptoms. Jackson expresses its attitude as follows: "Determining the proper time for operation is of great importance in the prognosis. Do not operate when the fluid is thin, serous, and contains flakes of fibrin. Operate when the fluid is distinctly purulent, rather thick and creamy, and does not sediment quickly in the glass syringe used for diagnostic puncture. Too early operation is a questionable procedure in post pneumonic empyema as observed here." The mortality here has been relatively low (20.5 per cent). At both MacArthur and Shelby the advice is against an early operation. At Camp Sherman a disagreement exists between the medical and surgical staffs as to the advisability of operation.

It is interesting that when the average mortality of the camps which favor an immediate operation is compared with that of the camps which prefer repeated aspirations there is no appreciable difference discernable in the statistical results. For example, the average mortality of the camps which prefer an immediate operation is 31.8 per cent and that of the other camps is 31.6 per cent.

In regard to the type of operation to be employed, the majority o the camps have preferred the more radical procedure of rib resection At Devens and Kearney, it is stated that only thoracotomy has been performed. At many of the camps the operative procedure has varied considerably to meet the apparent need of the individual case. For example, at Dix, Funston, Jackson, Logan, MacArthur, Meade, and Sevier, thoracotomy without rib resection has been done in the bad cases, to be followed later, if necessary, by rib resection. At Logan thoracotomy has been preferred in cases with thin fluid and contatectomy in cases with thick, fibrinous fluid. At Lee, the procedure has been to make a preliminary aspiration if the heart is seriously displaced or embarrassed by pressure, to be followed in a few hours by thoracotomy, or a slow drainage by means of thoracotomy and a fluted rubber drain of dental dam.

The average mortality of those camps in which costatectomy has been a routine has been 31.3 per cent; and the average mortality of the camps which have employed simple thoracotomy exclusively or primary thoracotomy, followed later by rib resection, has been 39. per cent. In practically all the camps, with few exceptions, local anesthesia has been used systematically.

The reports on the use of antistreptococcus serum are exceedingly scanty. In general, its use has been limited to only occasional cases in a few of the camps.

Postoperative continuous negative pressure has been used in only one camp (Kearny) and good results are reported to have been obtained with it.

Rather extensive use has been made of antiseptics of various kinds and irrigating solutions in the pleural cavity. At seven camps, however (Dix, Doniphan, Hancock, Meade, Sheridan, Upton, and Wadsworth), no solutions have been used. The substances most often employed have been the newer chlorine-containing antiseptics. Chief of these has been the so-called Dakin's solution, which has been tried in 17 of the camps. In general, it is stated that no remarkably beneficial results were obtained with Dakin's solution or any other antiseptic except to diminish the odor of the discharge. Three camps, however (Kearney, Logan, and McClellan), are enthusiastic in their reports on Dakin's solution. At Dodge and Funston, it was considered that the use of Dakin's solution diminished the discharge and at Gordon, it was thought that the patients who received Dakin's solution appeared less toxic than the others. Sherman emphasizes the point that the results with Dakin's solution are not so good if the drainage is not free, and at Cody it was found that in a few cases the temperature was elevated after its use. At Lee, it was considered that there was no apparent clinical effect of 16 cases, in which dichloramine–T was used. At Dodge, dichloramine–T was used in one case and was followed by complaint of pain. At Travis, after an extensive trial with a number of antiseptic solutions (including Dakin's), it was decided that the most satisfactory procedure was washing the cavity with saline solution followed by the injection of 2 per cent formalin in glycerine. Autogenous vaccines at Beauregard were found to be of no appreciable benefit.

Prophylactic measures have, in general, been of two kinds (1) the use of antiseptic mouth washes, gargles, and sprays in the measles cases, and (2) the insolation of the empyema cases. In all but six of the camps (Dix, Dodge, Doniphan, Grant, McClellan, and Wheeler), some sort of antiseptic mouth wash or spray has been used. Various preparations have been used, chiefly Dobell's solution, or some other mild antiseptic. At Custer, in one ward of 58 cases of measles, Dakin's solution was used as a nasal and throat spray twice daily, and a control ward received no spray. No difference in the incidence of complications after measles was noted, but the number of treptococci in the throat was decreased in the treated cases, as shown by biweekly cultures. In sprayed cases not in the hospital the same decrease in the number of streptococci in the throat was noted. A nasal spray of dichloramine–T has been used at Greene, Shelby, Upton, and Wadsworth. At Upton, however, it was discontinued "on advice of specialists." No reports are given as to its effects in any of the camps which have employed it. At Funston, streptococci has been given to the measles patients on the first, fourth, and eighth days after admission to the hospital as a prophylactic measure against measles-pneumonia.

Many of the camps have practiced insolation of the empyema cases after operation. At Beauregard, Cody, Custer, Dodge, Doniphan, Funston, Gordon, Grant, Hancock, Jackson, Kearny, Lee, Meade, Sevier, Travis, and Wheeler, attempts have been made to group the empyema cases either in separate wards or separate buildings. In addition to this, at Cody, Custer, Dodge, Gordon, Grant, Kearny, Logan, McClellan, Meade, and Shelby, the cubicle system of housing either in the separate wards or on the porches has been employed, and an attempt has been made to provide each patient with 1,000 cubic feet of air space. At Custer, the ward surgeons, nurses, and attendants have worn gowns and caps; and at Grant, masks and gowns have been worn not only by all the hospital personnel connected with these cases but also by the ambulatory patients. At Wadsworth, "semi-insolation in small rooms in the surgical wards" has been used. At Upton, such patients have been segregated at one end of the wards, head to feet, because of lack of space to provide separate wards.

The division of surgery has actively participated in conference on reconstruction, furnishing what counsel and judgment seemed to them to be wise in mapping out this intricate and important line of activity.

The division has kept in very close touch with the problem of antiseptics, both through personal contact with the Rockefeller

Institute course and through the sending of the general surgical personnel in attendance upon this course.

In a literary way the division has been active along two or three different lines. In the first place, it has an integral representation upon the board of publications; it has edited a manual on "Surgery of the Zone of Advance"; it has likewise edited a manual on "Lessons from the Enemy"; and it has seen to it monthly that the "Review of War Surgery and Medicine" carried to the surgical personnel digests of the latest approved surgical practices of our allies in the war zone. This monthly Review contains medical laboratory and various specialty subjects which are necessary for the entire personnel of the Medical Corps. The division was allowed, up to June, to distribute only 500 copies of the Review per month, but from June on an allotment of 5,000 per month has been secured.

There is being prepared under the direction of the division of general surgery a "Manual of Applied Surgical Anatomy," which will furnish in diagrammatic, easily visualized form, with a minimal amount of text, the essentials of anatomy.

VIII. Division of Military Orthopedic Surgery.

1. ORGANIZATION OF WORK.

The need of adequate preparation for the rehabilitation of the crippled soldier was recognized by the orthopedic surgeons of this country as early as the spring of 1916, when the two national organizations each appointed a committee on preparedness, the work of the two committees being coordinated through the choice of a common chairman. This made it possible, on our entrance into the war, to present a comprehensive plan for the organization and equipment of orthopedic hospitals for reconstruction purposes as well as to point out the lines along which subsequent study of the problem should be made.

In May, 1917, the chairman of the above committees was commissioned and sent abroad to study and report on conditions there. In July one officer, and shortly after a second one, was assigned to the Office of the Surgeon General for the study and coordination of the various activities in this special branch. Later in the same month an orthopedic advisory council was formed.

The report of the officer detailed to the study of the various phases of reconstruction work in Europe was made on his return in August and covered the location and equipment of hospitals, facilities for curative workshops and industrial reeducation, the selection and manufacture of splints and appliances, and the placing in employment of the disabled. Since this study had shown that a very large percentage (from 30 to 40 per cent) of the casualties of the present war had required special orthopedic treatment and that a large part of these, when so treated, had been restored to military usefulness, a division of military orthopedic surgery was created, a classification of conditions to be considered orthopedic, this being practically the same as that in use by the British Government.

Recognizing the value of the curative work as developed in the orthopedic hospitals in England, a vocational educational committee was formed, and as a result of its recommendations the division of special hospitals and physical reconstruction was authorized, whose function it should be to establish a broad plan of reconstruction comprising all departments of medicine and surgery involved in the problem. Since then the division of military orthopedic surgery has confined its work to professional problems.

2. PERSONNEL.

During the year 670 officers have been assigned to active duty 148 of these having been sent overseas and 88 attached to units already mobilized.

3. INSTRUCTION.

Special training has been given to 467 officers. This training has consisted of three kinds: (1) An elementary course chiefly in foot care and splint work; (2) an intensive course in fundamental principles of about six weeks' duration, given at the Army Medical School and at various other university centers; and (3) postgraduate work in orthopedic hospitals.

4. PUBLICATIONS.

The following books and articles have already been published by the division (others are in press):

BOOKS.

Manual of Orthopedic Surgery (War Manual No. 4) (revision now in press).

Manual of Minor Foot Ailments (two editions, the second including a section on shoe fitting).

ARTICLES.

"Splints for use in the advanced zone." (War surgery in the zone of advance.)

"After-care of nerve injuries." (For the division of head surgery.)

"Relation between the amputation and the fitting of the artificial limb."

"Temporary artificial limbs." (These two appeared in the Military Surgeon and reprints were secured for distribution to Army surgeons.)

"Foot care in military service." (Published in the Marine Corps Gazette.)

"Practical points in the use of immobilization in war surgery."

"Nonoperative aspect of the treatment of nerve injuries."

"Fixation methods for fracture of the spine." (Published in the Review of War Medicine and Surgery.)

5. SPLINTS.

It seemed wise to choose the splints already tested in military work by the British; these were simple in design, limited in number, and well adapted to meet the military demands. They were officially adopted, therefore, with the approval of the division of general surgery, in September. A few minor changes in construction were made in May, 1918, to increase efficiency and facilitate production.

6. CAMP ACTIVITIES.

The promotion of foot efficiency has always been regarded by the division as unquestionably its most important contribution to the winning of the war. For this reason the greatest insistence has been laid from the first on the work of the orthopedic surgeons in the camps and particularly upon the problem of prophylaxis. Systematic instruction in and treatment of orthopedic affections of a military nature, especially those of the feet, have been carried out by the attending orthopedic surgeons assigned to the various camps and under the direction of the supervising orthopedic surgeons in charge of the different camp groups. Arrangements have been made to utilize the services of chiropodists as far as possible in the treatment of minor foot ailments. Special attention has been given to all the phases of the shoe problem, and the constant endeavor has been made to cooperate to the fullest extent with the Quartermaster's Department in the supply and fitting of shoes.

7. ACTIVITIES IN THE AMERICAN EXPEDITIONARY FORCE.

The work abroad is developing rapidly and along much the same lines as in this country. The following points deserve special mention. Through the cooperation of the general and the orthopedic surgeons, a splint board was established in September, 1917, and the splints to be used limited to seven standard types; a manual of splints and appliances was also issued.

As a further step in standardization the orthopedic surgeons have been given supervisory control of splint treatment. A training battalion has been organized to facilitate the care of the physically defective, particularly those with weak feet, and is now working efficiently. By this means a large number of defectives have already been returned to the line. A further advance in foot care has been made by the assignment of orthodpedic surgeons for this work to the division. The first orthopedic unit has already been sent abroad, and the plans for the hospital are well under way. In these and other ways the work is being so coordinated as to insure continuity of treatment.

8. RECONSTRUCTION WORK.

What may be rightly designated as our first step in the actual work of reconstruction was taken shortly after our entrance into the war by the organization of a group of 20 well-trained orthopedic surgeons, at the request of the British, to assist them in carrying on this work in England. A second group of over 40 was sent in October, and a few others since then. This has proved of great value in the training and development of our men for the work both in France and at home.

Cases requiring orthopedic reconstruction develop during the training period as well as in combat. Plans have been made to include both, and the work is now under way at the Walter Reed and other hospitals.

The artificial-limb problem has been studied carefully from every aspect. An experimental department was authorized in November, 1917, and the work along this line is now well under way. The most recent views on the relation between the amputation and the fitting of the artificial limb have been published and distributed, as have also the details of construction of temporary plaster limbs. An artificial limb of modern type, but less expensive construction, which is adjustable both for length of limb and size of stump, and which can be manufactured in large quantities, is now being thoroughly tested in the department established for these cases at the Walter Reed Hospital. It is proposed to use such an appliance as a provisional one to enable the soldier to return to duty or to take up vocational training at a very early date before the stump is in suitable condition for the application of a permanent limb. Such an appliance will also be of advantage in case the number of the amputated should be very great. A work appliance for the arm has now also been devised by the department, and arrangements are being made to have it manufactured for our use. The artificial-limb industry in this country has been studied with a view to rendering the manufacturers all the assistance possible in the standardization of methods and equipment, the securing of supplies, and the training of workmen. Every effort has been made to keep in close touch with the manufacturers, both individually and through the official representatives of the Artificial Limb Makers' Association of the United States.

IX. Division of Surgery of the Head.

1. SUBSECTION OF OPHTHALMOLOGY.

1. *Procuring of personnel.*—Additions to the lists of ophthalmologists available for service originally secured by the subcommittee of ophthalmology have been obtained by (*a*) personal efforts on the part of the officers of the section, (*b*) by calling on those who in their questionnaires originally returned have offered service "at a later date," or "in the event of emergency," and (*c*) by a systematic daily examination of the papers of men seeking admission to the Medical Reserve Corps, which contained notice that they were "qualified in ophthalmology," and obtaining from the personnel division permission to retain them for ophthalmology.

In October, 1917, officers of this division were ordered overseas to inspect the hospitals of the American Expeditionary Forces as to their facilities for surgery of the head. This inspection included all except three of the American base hospitals in operation at that time (from Nov. 19, 1917, to Jan. 31, 1918), three Red Cross hospitals, and one naval base hospital, and by permission obtained through military channels a number of base and general hospitals in the British service and one French hospital sector from the base to the front. Opportunity was also afforded to visit general and special hospitals in England and to study the methods of caring for blinded soldiers in France and England, and finally, to investigate the best means of supplying our soldiers with spectacle lenses and the advantageous places for establishing the optical units. Complete reports of this work were made to the chief surgeon in France and to the Surgeon General and are on file.

Equipments.—During the year constant attention was paid to the standardization and selection of instruments, material, and facilities for the subsections of ophthalmology in the various base hospitals, and an endeavor was made to list the minimum quantities of drugs regarded as necessary for eye work per quarter in the base hospitals.

The plan originally in operation whereby the enlisted men secured, after proper examination by the ophthalmologist on duty in the subsection of ophthalmology, a standard pair of spectacles through the post exchange of each cantonment, was modified in this respect, that the glasses are now furnished free of charge on prescription filled by selected firms of opticians (G. O. 35, par. 7). Wherever required, an enlisted man with the training of a practical optician was attached to the subsection of ophthalmology of the base hospital.

The mobilization of one central optical unit and eight auxiliary units was completed, and on order of Gen. Pershing these units were sent overseas under the command of Maj. Allen Greenwood, Medical Reserve Corps, who was in special charge of this work, and are now in satisfactory operation. In addition to ground lenses, glass and grinding machines, the equipment of these units included a quantity of artificial eyes.

An investigation instituted by the subsection of ophthalmology, with the aid of Dr. Day of the geophysical laboratory and Bureau of Standards, resulted in the demonstration that glass can be made in this country suitable for the manufacture of artifical eyes. Such glass has been produced, and from it artificial eyes have been manufactured.

2. SPECIAL BASE HOSPITAL 115.

Pursuant to the authorization of the Surgeon General for the development of a base hospital particularly devoted to surgery of the head, to be established in France, Special Base Hospital No. 115 was organized at Cape May in February, 1918, and during the year much attention was given to its equipment and personnel. The call for this hospital was received on May 24, 1918, and the arrangements entirely completed by June, 1918. Now mobilized at Cape May, its personnel and equipment are ready for transportation overseas.

3. SECTION OF OTOLARYNGOLOGY.

PROCURING OF PERSONNEL.

The first activity of the section of otolaryngology after the formation in the office of the Surgeon General of the division of surgery of the head was to continue the work already started by the subcommittee of otolaryngology of the Council of National Defense and apply the results of this committee's labors. The chief business of this committee consisted in sending out questionnaires, filing and indexing them when they were returned, distributing the application papers for the Medical Reserve Corps of the Army, and advising on the rating of the applicants as their papers passed through the Surgeon General's office. The questionnaries resulted in a catalogue of the otolaryngologists of the country who were available for immediate or deferred service. In most cases the questionnaires gave sufficient data for rating the applicants. Where, however, there was doubt application was made to members of the profession in each State who had been selected to act as State consultants.

The personnel of the various cantonment base hospitals was selected from these men and assigned to duty. During the year that has elapsed since the formation of the division of surgery of the head the securing of adequate personnel and the attempt to place it efficiently and agreeably has been the main work of the section of otolaryngology. In order to bring this about much correspondence has been carried on with otolaryngologists seeking information about the service and many consultations have been held in the

Surgeon General's office with physicians whose desire to do their part brought them to Washington for advice.

In May, 1918, a circular letter was sent to 100 otolaryngologists who a year ago expressed their willingness to enter the Medical Corps at a later date should their services become necessary.

Coincident with the enrolling and assigning of otolaryngologists to the base hospitals in this country a tentative list of assignments for base hospitals abroad was drawn up.

SPECIAL BUILDING.

A special building for the section of surgery of the head was designed jointly by the section of otolaryngology and the section of ophthalmology for use in this country.

The special hospital at Cape May, called No. 115, has been assigned its personnel in otolaryngology and its special equipment in this line. The permanent staff at Cape May also has been assigned its otolaryngological staff.

EQUIPMENT.

A working set of instruments for the section of otolaryngology was prepared and the instruments supplied to the base hospitals. This list has recently been modified and extended and standardized. An instrument list for a special head hospital abroad, should one be called for, was drawn up also, and the section of otolaryngology took a proportionate part in planning the special hospital building for the head hospital abroad.

STANDARDS FOR EXAMINATION OF REGISTRANTS.

In connection with the examination of the registrants of the draft the standard of hearing for admission to the Army was revised, and the tests for malingerers amplified. Later the regulations for medical advisory boards, as far as they concerned otolaryngology, were revised and rearranged.

An abundant supply of instruments and teaching paraphernalia has been recommended for the use of the school. It is hoped that this school will be allowed to develop, as it will fill a large place in rating men in the specialty of otolaryngology and in acquainting them with modern methods of diagnosis and treatment.

4. SECTION OF PLASTIC AND ORAL SURGERY, JULY 24, 1917, TO DECEMBER 30, 1917.

ORGANIZATION OF THE SECTION OF PLASTIC AND ORAL SURGERY, WITH DEFINITION OF ITS FUNCTIONS.

This was started in July, 1917, by the joint committee on head surgery, Council of National Defense, with the approval of the Surgeon General.

It was decided that the surgeon in charge of oral surgery should have the care of injuries and surgical diseases of the mouth and its essential structures, including the bony framework and soft tissues of the face, and also of the neck when the major part of the injury is situated above the clavicle, with the exception of certain injuries and surgical diseases coming within the province of the ophthalmologist, the otolaryngologist, and brain surgeon.

FORMULATION OF PLANS TO SECURE THE SERVICES OF PERSONNEL FOR THE SECTION.

Letters were sent out to over 200 of the more prominent surgeons, asking for suggestions as to individual men whose training and practice are such as to make them especially fitted for the section of plastic and oral surgery. At the same time inquiries were started as to available dental oral surgeons. Letters and questionnaires were sent to surgeons and dental surgeons possibly suited to work with the section. Up to the end of the year 1917, 147 surgeons and 117 dental oral surgeons had been selected and classified for this work.

PUBLICATIONS.

After a complete survey of the war literature a consultation was held to decide the most effective means of placing this at the disposal of the men who were to do the plastic and oral surgery. It was decided to incorporate this material in the third edition of Blair's "Surgery and Diseases of the Mouth and Jaws," because, on the one hand, time did not permit a full exposition of the subject in a special manual, while, on the other, it would be of less utility and somewhat awkward to attempt these observations while disregarding the general principles upon which they are based.

Each hospital organized for service in this country or abroad is to be furnished with a copy of this book.

SPECIAL COURSES OF INSTRUCTION.

Three schools, with special courses of instruction in plastic and oral surgery for officers assigned to the section were authorized by the Surgeon General and established at Washington University, St. Louis; University of Pennsylvania, Philadelphia; and Northwestern University, Chicago.

Some of the personnel of the section have also been sent to special courses at the Rockefeller Institute, New York, and at the Mayo Clinic, Rochester, Minn.

INSTRUMENTS AND EQUIPMENT.

The section worked continuously upon the selection, simplification, and standardization of instruments and equipment to be used by the men who are to do this work abroad.

Both on general surgical principles and upon facts gleaned from the war experiences of others the section of plastic and oral surgery has been convinced that if these jaw cases could receive early effective treatment, much suffering, convalescent time, and not a few lives could be saved, and it is making every effort to place members of these oral surgical units in the most advanced operating stations and provide them with proper equipment for instituting early care of the cases, a plan that has received the sanction of the Surgeon General. To facilitate the work of these men at the advanced stations, a simple, easily applied, universally applicable jaw splint for temporary use is being worked upon.

5. SECTION OF PLASTIC AND ORAL SURGERY, JANUARY 1, 1918, TO JUNE 30, 1918.

PROCURING OF PERSONNEL.

Additions are gradually being made to the personnel of the section from newly commissioned officers in the Medical Reserve Corps and by the association with them of members of the Dental Reserve Corps. The total number is not increasing rapidly owing to losses incurred through transfer of officers to other divisions, unsuitability for the work, and military emergencies.

6. SECTION OF BRAIN SURGERY.

The section of brain surgery, division of surgery of the head, was established in the Office of the Surgeon General, July, 1917, the work beginning with the assignment for duty of a neurosurgeon, who was later commissioned in the Medical Reserve Corps.

PERSONNEL.

Two hundred and fifty medical officers were authorized for this section and steps taken to collect the group. Questionnaires were mailed to many representative surgeons throughout the country as well as requests to the leading general hospitals to forward the names of members of their staff interested in brain surgery or having a large casualty practice. These surgeons were then sent a questionnaire, information being requested if they would be willing to be classified in this section. All answering in the affirmative were to be retained upon acceptance of commission, or if already commissioned an exemption was placed on their card in this office. With the assistance of the medical men appointed as advisors for the various districts, certain of the surgeons answering the questionnaires were selected to be given instruction in neurosurgery. The first school was organized at Philadelphia, University of Pennsylvania.

CLINICAL, NEUROSURGICAL.

In addition to the regular assignments to the base and general hospitals in this country, officers have been assigned temporarily at hospitals for consultation.

September 24, 1917, the first edition of "War Surgery of the Nervous System" was published and copies sent to the various hospitals and officers retained by the division of brain surgery. This publication was a treatise on the anatomy, physiology and surgery of the nervous system, combined with a survey of the literature on brain surgery of the present war. February, 1918, a revision of the first edition of "War Surgery of the Nervous System" begun.

LABORATORY, NEUROSURGICAL.

The Army neurosurgical laboratory was established in order to investigate certain problems arising from infections and injuries of the central nervous system in war. The first problem confronting the investigating staff was the production of experimental infections and lesions comparable to or identical with those of the war zone.

The second task was the testing out of previously recommended therapeutic measures and the subsequent modification of the procedures to effect a cure of the experimental condition.

There have been produced in this laboratory during the past six months, experimental lesions of the central nervous system as follows:

(*a*) *Meningitis.*—This generalized infection of the central nervous system has been brought about in three ways: (1) The direct injection of organisms into the subarachnoid space; (2) by intravenous injection of organisms followed by release of cerebrospinal fluid; (3) by massive intravenous injections of certain very virulent bacteria. The lesion produced is identical with the condition in man, and the clinical picture of the disease analogous. Both acute and chronic forms of the infection have been caused, the character being dependent upon the dosage and the strain of the organism used.

(*b*) *Abscesses of the brain.*—These have been caused by: (1) The direct injection of pyogenic bacteria into the cerebral cortex or (2) the penetration of the skin, skull cap, etc., by an instrument giving a wound similar to that of a low-velocity missile. Acute and subacute forms have been occasioned, some remaining a local infection and others developing into a meningitis. The experimental lesion is wholly similar to that in man.

(*c*) *Sterile injuries to the brain.*—These have been caused in different ways in order to give histological control both for the pathological conditions and for the subsequent therapeutic repair of cerebral defects.

(*d*) *Hydrocephalus* (*internal*).—By the intraventricular or subarachnoid injection of certain granular materials, an internal hydrocephalus, comparable in every way to that following meningitis in man, has been caused both in adult and young animals. The relief of hydrocephalus and increased intracranial tension presents one of the greatest problems in neurological surgery.

Therapeutic measures for the relief of the experimental infections have been undertaken, as well as procedures looking to the localization of an infection to an abscess. Irrigation of the subarachnoid space with bland solutions have resulted in the apparent cure of a few animals, to which lethal doses of bacteria had been administered within the nervous system. In the majority of cases, such irrigations have merely, on single administration, resulted in a prolongation of life of about 100 per cent as compared to the control.

The toxicity of certain antiseptics within the subarachnoid space has been determined on animals. No evidence has been brought forward as yet to demonstrate beneficial effects of these chemicals when used in doses below lethal concentration. It is doubtful if antiseptics will yield benefits when used in generalized infections of the nervous system.

In experiments concerning the repair of the bony skull after injury, the possible use of fresh sterile bone, of boiled bone, of autoclaved bone and of formalinized bone has been demonstrated. All varieties mentioned are capable of yielding firm union with the rest of the skull.

The histopathological control of the various experimental lesions in the animal has been carried along. Likewise, some histological studies have been made in this laboratory on animals with experimental shell shock.

X. DIVISION OF NEUROLOGY AND PSYCHIATRY.

The importance of nervous and mental disease had always been recognized by the medical department and medical officers had been regularly detailed to St. Elizabeths Hospital for training in the principles and practice of psychiatry. But before the war the Army was too small and too much spread out to render it possible to establish this highly specialized branch of medicine as an integral part of the medical policy. The experiences of the past year, however, have shown the military and economic necessity of excluding from fighting forces nervously undependable and unreliable persons, and it would seem now to have been definitely demonstrated that neuropsychiatrists should constitute about 3 per cent of every Army Medical Corps, and that they should be particularly well represented at all points of enlistment.

The chief functions of a neuropsychiatric department are therapeutic and preventive; of these the therapeutic is the least important from a purely military point of view, because the number of soldiers who break down nervously under service conditions and who can be returned to duty in a reasonable length of time is small as compared with those who break down for purely physical reasons. There are certain nervous episodes, certain intoxications, notably delirium tremens, prone to make their appearance during mobilization, which rapidly disappear under treatment and leave the patient apt for military life. But in an army under training the number of soldiers admitted to base hospitals who after treatment return to full duty is regrettably small. This statement must be modified in so far as the neuroses, "shell shock," of the present fighting is concerned. These nervous breakdowns show a satisfactory percentage of recoveries provided certain fundamental conditions are fulfilled. These conditions are based on the fact that a sound man nervously shaken has a much better chance of getting well promptly if the circumstances of his environment are shaped to convince him that his injuries are neither serious nor permanent. As the French were quick to perceive, this result is obtained primarily by an administrative policy which will not recognize neurosis as a cause for discharge from military service, and which insists that all such cases be kept away from the hospitals where the "gros blessés" are sent. It insists further that the treatment of such cases, which is largely a treatment of brief rest, encouragement, and reassurance, be carried on near the front. These arrangements combat from the outset the idea in the mind of the injured soldier that the injury is of a disabling character. Such an idea would have scant chance of becoming a compelling force in a soldier's conduct if it could be proclaimed throughout an army that the war neurosis was not a condition which entitled the soldier to a pension. It might not be wise to recommend such a regulation at this time, but it is believed that such a regulation, while it would work injustice to some, would reduce the severe and protracted war neuroses to almost negligible quantities and in the end would be a humane measure.

With the exception of the war neuroses, the chief military importance of the therapeutic activities of the neuropsychiatric branch of the medical department is the increased effectiveness in evacuation it insures. The prompt diagnosis of cases, and clinically wellfounded recommendations as to the proper disposition of them, results in a speedier evacuation than is possible otherwise, and leaves available more hospital beds.

From a purely humanitarian standpoint the treatment of nervous and mental disease has proved as satisfactory, if not more so, than the treatment of similar conditions in civil life. The regularity enforced by army conditions is an excellent tonic for psychoneurotics under treatment. The treatment of the insane has been particularly successful. It was evident from the outset that the insane could not be properly taken care of in the general medical services of the cantonment hospitals. Wards were established at these hospitals for temporary care, but arrangements were made by means of which soldiers and officers presenting the symptoms of insanity could be transferred promptly to special centers, which centers were located at San Francisco, San Antonio, Atlanta, Des Moines, Washington, and Buffalo, points of densest military population. These centers serve as psychopathic hospitals, where patients are retained as long as it appears there is a chance for their recovery. The personnel, both commissioned and enlisted, was selected by reason of their experience with patients of this class. The equipment with hydrotherapeutic and electrotherapeutic apparatus is of the most approved character. The actual operation has been gratifying in the extreme. A large number of patients have been returned to their friends or to independent life without having been officially regarded as insane. As is well known, the military psychoses, if properly treated, have a short clinical course and a favorable outcome, which enables a hospital to handle a large number of patients. Fort Porter, at Buffalo, for example, with a capacity of 155 beds, can dispose of 1,200 patients a year. A large number of the States have kindly cooperated with this office in receiving back insane recruits from their States.

But the real value to an army of neuropsychiatrists is the prevention of the occurrence of nervous and mental disease among troops, a prevention which is accomplished by the barring from enlistment of all men actually suffering from these limitations or strongly predisposed to them. This group which comprises, as established by civil statistics, from 1 to 5 per cent of the total male population in draft age, is composed of the same class as the immigration laws bar from admission to the United States. The diseases or conditions which handicap them, as established by the statistics collected by the military psychiatrists of the Army, in order of frequency are feeble-mindedness, epilepsy, insanity, and psychopathic constitutional make-ups, which make it as difficult for the person so made up to succeed as it is for a clubfooted man to walk evenly. Alcoholism is less prominent than it once was in armies, and, with the exception of syphilis of the central nervous system, organic nervous diseases are so rare as to be practically negligible quantities. Cases of the above character the neuropsychiatric boards have recommended for rejection or discharge, and the actual discharges made on recommendation of general disability boards for these causes has varied from 1 to 2 per cent. The rapid influx of registrants of the second draft has overtaxed the personnel, and the examinations have been less thorough than for the first draft.

The highest percentages of disqualifications have been found at the recruit-depot posts. It would thus seem that a cross section of American young men, as represented by the draft army, contained a smaller percentage of undependable persons than are found in an equal number of volunteers. This fact may have some bearing on the relative value of services en masse which are offered and those which are required by law. An indication of the extent of its military and economic advantage attained by keeping out of the Government service those who would, with considerable certainty, break down in the service and become a charge on the Government, is furnished by the following: St. Elizabeth's Hospital in Washington is the one Government institution permanently authorized to give custodial care to the insane of the military services. It is, in a way, a barometer of the mental health of the Army. Admissions to it from the various military posts give a fairly accurate idea of the extent of mental instability among the troops. From previous experiences, it has been estimated that the mobilization of a million men would involve the commitment to St. Elizabeth's, or to some similar institution, of at least 2,000 soldiers. As a matter of fact, the number of such custodial cases resulting from the first million was 177. Neither were they sent back to State hospitals. The total of admissions (for the first million) to State hospitals was 300. In other words, there were produced in approximately eight months, from the mobilization of an army of 1,000,000, instead of 2,000 to 3,000, only 477 cases. There is little reason to doubt therefore, that the neuropsychiatric examinations served a double purpose. On the one hand, they have kept out of the Military Establishment men who would become charges upon the Government without having rendered it material service, and, on the other hand, from the humanitarian standpoint, it seems clear that a smaller number of soldiers became insane, than has been the case in armies when no effort has been made to exclude the unstable. (It is pertinent to remark in this connection that the number of delinquents has fallen much below what was expected.) It would seem, therefore, that military service actually initiates mental unbalancement in predisposed persons which would not occur if such service were not required. Contrary to the general rule of the improvement in health of recruits under training, members of this particular class do not improve, but, on the contrary, a potential condition becomes actual.

Another function of psychiatrists has been to assist in the attainment of military justice. As in military life, perhaps even more than in civil life, a goodly proportion of offenders, expecially in such offenses as desertion, stealing, persistent failure to obey orders, are mentally affected in some way to a degree that they can not reasonably be held responsible for their delinquencies. In such cases punishment is not corrective, and consigning such irresponsible persons to prison for long terms has no purpose and commits the Government to wasteful expense. In the consideration of cases of this character, either for the purpose of determining the advisability of trial or as witnesses at courts-martial, the psychiatrists have been frequently called upon by judge advocates. It is hoped that this cooperation will become progressively closer.

The administrative arrangement of the neuropsychiatric work consists of a division of neurology and psychiatry in this office.

This division initiates the orders by which the officers proceed to their various stations and suggests the duties for which the individual officers are best fitted. These serve in base and other hospitals and as examiners on neuropsychiatric boards which are formed from time to time as occasion arises. In January, 1918, the General Staff created the position of division psychiatrist, one for each tactical division, with rank of major. The official attachment of these officers is to one of the field hospitals, but they generally have been given a desk in the office of the division surgeon, from which point they can operate most effectively. It is their duty to keep in touch with the mental state of the command, to further the prompt evacuation of the unfit and to see that, proper treatment is provided. These officers come to know the personnel well and are in position to tell which officers or men are the least likely to withstand the great strains of modern warfare. Reports from the expeditionary force indicate that they have been a great assistance in preventing the occurrence of the war neuroses by their knowledge of the troops with whom they have already served for months during the training period.

In addition to the division assignments, neuropsychiatrists are, detailed to base, special, and evacuation hospitals for over-seas service and are also sent as casuals and in replacement, to be recommended for assignment by the senior consultant in psychiatry, American Expeditionary Forces. Practically all of the officers, under the general direction of the division of neurology and psychiatry, are commissioned either in the Medical Reserve Corps or the National Army. They were men who had already attained distinction in their specialty in civil life or more recent graduates who had taken up this specialty only a short time before war was declared and who perfected their special knowledge through their military experience. It would be difficult to speak too highly of the way all have conducted themselves under their new conditions. They have shown themselves eager to learn and willing to forget what they used to know, when former knowledge or ways of doing proved incompatible with the military situation.

XI. Division of Psychology.

Committees of the American Psychological Association and the psychology committee of the National Research Council prepared, between April and August, 1917, various psychological methods for the selection and classification of recruits in the Army and Navy. In August, 1917, on recommendation of the National Research Council, certain methods were accepted for trial which had been devised especially for the psychological examination of men enlisted in the United States Army. The chairman of the psychology committee of the National Research Council was appointed, on August 17, major in the Sanitary Corps to organize and direct this new branch of the service for the Medical Department.

During the initial development of this service the chief of the division worked under the immediate administrative supervision of the chief of the division of neurology, psychiatry, and psychology. Plans were speedily prepared and the necessary authorization secured from the Secretary of War for thorough trial of the proposed methods in four National Army cantonments. For this work 16 psychologists were commissioned first lieutenants in the Sanitary Corps and 24 others were given civil appointment by special authorization of the Secretary of War. The psychological staff of each camp consisted of 10 men.

Between October 1 and December 1, 1917, nearly 100,000 drafted men, students in officers' training camps, and officers of camps or divisions were examined. In December the work was officially inspected by an officer of the Medical Corps. The reports of this inspectional officer supplemented importantly the statistical data supplied during progress of work. As the results of psychological examining indicated clearly the value of the work for the elimination of men mentally defective, the balancing of organizations in mental strength, the classification of men for the assistance of personnel officers in the camps, and the indication of men of exceptional intelligence to be charged with special responsibility or sent to officers' training camps, and as all reports of the inspector were favorable, in December, 1917, the continuance and the extension of psychological examining to the entire Army was recommended to the Secretary of War. This recommendation, after careful inquiry concerning the value of the work by the training committee of the War College division of the General Staff, was approved by the Secretary of War, who directed the Surgeon General to prepare a plan for the proper conduct of the proposed work.

A comprehensive plan was promptly prepared by the staff of the section of psychology, division of neurology, psychiatry, and psychology. This plan provided for suitably trained personnel, special psychology building in each camp, and necessary apparatus and printed materials. It was fully approved by the Secretary of War January 19, 1918. This office was authorized to create a division of psychology and to put the plan of psychological examining into effect.

A school for military psychology was immediately organized in connection with the medical officers' training camp, Fort Oglethorpe, Ga., in which a maximum of 100 student officers and approximately 100 psychologists enlisted in the Medical Corps could be trained simultaneously during a period of two months. This school was opened February 4 with Capt. William S. Foster, Sanitary Corps, National Army, as senior instructor. Between this date and July 1, 1918, approximately 70 officers of the Sanitary Corps and 250 men enlisted in the Medical Corps were given special training in military psychology.

Plans for suitable psychology building were prepared and duly submitted to the Quartermaster General. Subsequently the equipment committee of the General Staff disapproved the expenditure for these buildings pending congressional appropriation for the purpose. The Secretary of War directed that existing buildings be assigned for psychological examining in most of the divisional training camps.

The necessary apparatus and printed materials for the examining of 500,000 soldiers were speedily prepared, and during April and May psychological examining staffs were organized in 25 National Army and National Guard camps. During the month of June additional apparatus and printed materials were manufactured for the examining of 1,000,000 soldiers.

On July 1, 1918, psychological examining was in progress in 28 Army camps and in 3 general hospitals. Seventy-nine officers of the Sanitary Corps were on duty in these stations and in the division of psychology, Surgeon General's Office. Approximately 100 noncommissioned officers and privates of the Medical Corps especially trained in military psychology had been assigned to duty in examining stations, and somewhat more than 100 were in training at the school of military psychology, Fort Oglethorpe. Up to April 27, 1918, when new methods were put into use, approximately 140,000 soldiers had been examined. On July 1, 1918, 600,000 had been examined. Of this number slightly more than one-fourth of 1 per cent had been recommended by psychological examiners to psychiatrists for discharge because of mental deficiency, and about one-half of 1 per cent had been recommended for assignment to service organizations or development battalions because of mental inferiority.

Psychological examinations which were originally conducted in wards of base hospitals are now made in psychology building located usually in the depot brigade. In this building drafted men are examined promptly on reporting to camp. Their intelligence ratings are immediately transmitted to the personnel officer of the camp. All cases of mental deficiency or those for which psychiatric examination is indicated as desirable are referred to the psychiatrist.

The aim of the division of psychology is to develop a psychological center in each military training camp to which all psychological problems of military assignment, training, discipline, morale, and intelligence may be referred by officers of the line or staff. Such a center exists in 25 camps, and the service is being extended as rapidly as available personnel permits.

XII. Air Service Division.

The office of the chief surgeon, air section, Signal Corps, was established by War Department, Order No. 207, September 6, 1917. From the beginning, the medical division of the air section has developed rapidly, and at the present has the following personnel:

Commissioned personnel, United States, including Dental Corps and Sanitary Corps officers	971
Commissioned personnel, overseas, including Dental Corps and Sanitary Corps officers	303
Enlisted personnel, United States	3, 730
Enlisted personnel, overseas	1, 114

One of the first duties of the chief surgeon's office was the selection of the flying personnel of our Army. For this purpose physical examining units were organized, through which all applicants for aviation were examined and selected or discarded, according to the individual fitness for this branch of the service.

During the early part of 1917, the aviation examining board of Washington, D. C., passed on approximately all applicants for commission in the aviation section, Signal Corps, but with the expansion of its commissioned personnel the number of units was increased until in January, 1918, there were 35 examining units established in the principal cities of the United States, which with 32 additional units established at National Army and National Guard divisional cantonments, made a total of 67 examining units.

From the month of February, 1918, the work of these units has gradually been terminated. Now, after a period of inactivity, a limited number of boards have resumed their functions. The examining unit serves two functions. Its medical personnel passes on the physical fitness of the prospective aviator, and the board tests his mental qualifications. A careful tabulation has been made of the results of the physical examination of all men who applied for detail as cadet fliers; 70.7 per cent qualified and 29.3 per cent were rejected. Separating the causes of disqualification into nine groups, the following rates based on the total number examined are obtained:

	Per cent.
1. Eye	5.9
2. Ear	1.2
3. Nose and throat	.8
4. Equilibrium	2.
5. Vascular system	2.5
6. Genitourinary system	.4
7. Other and general subnormalities	1.9
8. Disqualified in two tests	7.
9. Disqualified in three or more tests	8.6
Total	29.3

For any one cause of rejection the failure to meet the eye requirements easily leads, being 5.9 per cent. Visual defects were present in at least one-half of the cases where men failed in two or more counts. In other words, it is safe to assume that practically 50 per cent of those rejected failed to meet the eye tests.

In connection with the care of the fliers a special board has been established to study the effects of altitude on man, and its relation to deterioration of mental and physical activity. This special board is designated as the medical research board, air service, and consists of trained psychologists and medical men taken preferably from existing examining units trained in eye and ear examinations, particularly the rotation tests. It investigates all conditions which affect the efficiency of pilots, carrying out at flying schools and elsewhere such experiments and tests as will determine the ability of pilots to fly in high altitudes. It consists of a central laboratory at Mineola with extensions at flying schools. At present the work of the board is devoted to the training of examining units for the 10 laboratories wherein will be carried on the work of examining and classifying officers who will comprise the flying force of the Army, and which will establish the fitness of each man for that altitude in which he can best be of service.

Also, a natural outcome of the work of the office in connection with the welfare of the aviator in actual service has been the need of a medical advisor to the commanding officer. The military designation given to such an officer is flight surgeon. Each flying school is to have its flight surgeon, who is responsible for the "fitness to fly" of each individual aviator in the command. Others will be trained for service abroad as needed. Under the flight surgeon will be a physical director whose duty will be to have charge of the physical exercise and athletic training of the fliers in the command. The organization is now being completed for 50 flight surgeons, and in addition 50 physical directors. This personal supervision will tend to greatly increase the mental, moral, and physical efficiency of the flier, and is a consistent outcome of all policies pursued by the medical branch of the air service with regard to the selection and care of the air service personnel.

Respecting hospital construction and maintenance, the work has been mainly directed towards standardizing all medical department buildings for use at flying fields.

The following cantonment types have been developed:

1. Hospitals: Six-bed; 8-bed; 28-bed; 50-bed; 60-bed; 100-bed; 250-bed; 750-bed; 1,250-bed.
2. Medical Department enlisted barracks: Types for 30 men; 50 men; 60 men; 200 men.
3. Nurses' quarters: Types for 6 nurses; 12 nurses; 30 nurses; 60 nurses.
4. Medical research laboratory buildings.
5. Cold-storage buildings of three types have been developed for 1,000 men; 2,000 men; 5,000 men. These are cooling chambers in ice houses, and have been built at 20 of the southern fields.
6. Storehouses of two types, one for single unit and one for larger fields. These include fumigation chambers and the necessary shelving.

Two permanent hospitals are being constructed, one at Rockwell Field and one at Langley Field. These were designed by Mr. Kahn, of Detroit, Mich., and will be a credit to the service.

A 200-bed hospital, the Mary Imogene Bassett Hospital at Cooperstown, N. Y., was offered, rent free, to the aviation service for the recuperation of aviators, by Mr. Edward Severin Clark, of Cooperstown. The buildings will be completed about February 1, 1919. Included in the lease is the free use of the golf links, gymnasium, library, and club at Cooperstown.

All hospitals at all fields have been enlarged during the fiscal year, and separate quarters provided for enlisted men. Nurses' quarters at 21 of the single-unit fields have been delayed owing to their disapproval by the Secretary of War. It is hoped their construction will proceed shortly.

Steps have been taken to increase the ventilation in all barracks and hospitals in the aviation service.

The subject of providing quicker and more efficient handling of the injured, following crashes on flying fields, is receiving the consideration of the medical service, and the airplane ambulance is being developed. In all cases where the injured are in imperative need of an immediate operation, or must be moved with a minimum jolting, their transportation to the rear by airplane ambulance is important.

Experiments have already shown the following important facts:

(1) While an auto will cover a distance of 20 km. in an hour and a half, an aeroplan with the same load will do it in less than 15 minutes.

(2) All jolts which are so dangerous to the wounded, particularly to those suffering from wounds of the abdomen and thorax, and from fractures, are radically eliminated The shock of landing on rather bad grounds is much slighter than the jolt one gets i an automobile crossing over ruts or shallow trenches.

The aviation section, Signal Corps, ceased and determined upo the creation and organization of the Department of Military Aero nautics, pursuant to the proclamation of the President, dated Ma 20, 1918. The chief surgeon's office, aviation section, Signal Corps became the air service division, Surgeon General's Office. On th 30th day of June, 1918, there were 65 stations occupied by troop connected with aviation.

XIII. FOOD DIVISION.

The food division was established September 4, 1917.

The director appointed by the Surgeon General secured the services of an advisory committee. A meeting of this committee was held on September 29, 1917. The plan presented by the director for nutritional surveys of camps and cantonments was formally approved. The plan presented was set forth in a memorandum to the Surgeon General dated September 19, 1917.

On September 20, 1917, a conference was held in the office of the United States Food Administration, Washington, D. C., to consider questions relative to the subsistence of the Army. The Surgeon General of the Army, the Quartermaster General of the Army, a representative of the British Army, the Director of the Food Administration, and a number of other notable men who are engaged or interested in this class of work, were present. At the suggestion of the Surgeon General, the Director of the Food Administration was called upon by the chairman to outline the plans for investigation of the food conditions in the camps. There followed a general discussion of subsistence and waste in the Army camps, in the course of which a number of questions were asked regarding the plans of the food division. Such comments as were made were generally favorable to the plan.

Formal approval of the plan of operation outlined for nutritional surveys was obtained by an indorsement approved by the Secretary of War dated October 16, 1917, and on October 26, 1917, The Adjutant General addressed a letter to all the commanding generals of departments, National Guard, and National Army divisions, and the commanding officers of Coast Artillery districts, training camps, and independent stations on the subject of food surveys and inspections in the training camps and cantonments and hospitals of the United States Army, requesting authority to make the food surveys as outlined in the several posts, training camps, cantonments, and hospitals of the United States Army, and authorizing the necessary travel for this purpose.

Officers for the food division were selected mainly from the faculties of medical schools, university laboratories, and agricultural experiment stations, and were commissioned in the Sanitary Corps. They were given a brief course of training in Army procedure, in the conduct of nutritional surveys, and in gross inspection of foods. Later a course for nutrition officers was established at Camp Greenleaf.

The first nutritional survey was made at the ambulance service training camp, later known as Camp Crane, Allentown, Pa., the first week in October. Following this parties were made up and successively dispatched to other camps until early in 1918 the total number of parties had reached 10. Surveys were made and parties constituted as described in Table 156.

Results may be grouped under three heads corresponding to the three main lines of activity: (1) Inspection of food; (2) improvement of mess conditions; (3) study of the suitability of the ration.

1. INSPECTION OF FOODS.

Foods were inspected by nutritional survey parties at the subsistence storehouses and in mess houses, special attention being given to those classes of food not already inspected by the veterinary division or by representatives of the Bureau of Animal Industry for the Quartermaster Corps.

2. IMPROVEMENT IN MESS CONDITIONS.

Mess conditions were studied with reference to (*a*) sanitation, (*b*) efficiency, (*c*) economy, (*d*) satisfactory nutrition. Such reports as were made on sanitary conditions of the mess were made directly to the sanitary inspector of the camp. Many recommendations were made for improving the efficiency of the mess as judged by the completeness and state of repair of its equipment; by the cleanliness of this equipment; by the state of orderliness in the storeroom, the arrangement of foods in the refrigerator, the system of menus, the mess accounting, the amount of savings, and the training of kitchen personnel. Special attention was given also to the matter of food conservation and economic mess management. An illustration of the effect of a few days' special instruction in reduction of waste is seen in chart No. 71. The main object of the visits of survey parties to the mess was to assist in the adoption of such measures as would result in proper nutrition of the soldiers. Instruction was given in the construction of menus so as to insure a sufficient supply without excess of each of the important foodstuffs. Such instruction was most commonly given at conferences of the mess sergeants or mess officers of a single regiment.

3. SUITABILITY OF THE RATION.

Detailed quantitative surveys have been made of more than 300 messes scattered through more than 50 camps and extending from October to June. A page from the statistical summaries of these surveys is shown in Table No. 156. This exhibits the average energy value of food supplied, wasted, and consumed per man per day, the distribution of fuel value in the food consumed, the percentage of each foodstuff wasted, as well as the percentage of the total fuel value wasted, the cost of the food consumed per man per day, the value of the food wasted, and the actual average amount of total waste and edible waste. Studies have been made also at a considerable number of camp and regimental exchanges (chart No. 72). The actual average amount of nutrient materials purchased at the canteen has been estimated at 405 calories per man per day. This added to the total food consumption at the mess of 3,700 calories makes a grand total of about 4,100 calories, or 27.9 calories per pound for the average soldier. This agrees with the theoretical requirement of energy necessary to enable a soldier of average weight to do a maximum piece of work, such as a march of 30 miles in 10 hours carrying a pack and other equipment weighing 44 pounds. If a soldier does not do this maximum quantity of work the fuel energy accumulates in his body in the form of fat, the muscles also hypertrophy, and the result is a considerable gain in weight. The average gain estimated in four different camps (Devens, Grant, Dodge, and Funston) amounts to 7½ pounds in three months.

The nutritional surveys were calculated to exhibit not only the actual average amount of food consumed but also the average amounts of various articles composing the ration as selected. Table No. 157 shows in parallel columns the amount of each article of food prescribed by garrison ration (A. R. 1221) and the actual average amount of each of these components and substitutive articles selected in 227 messes (Table No. 157). As a result of these studies the food division has proposed that the garrison ration be modified in accordance with

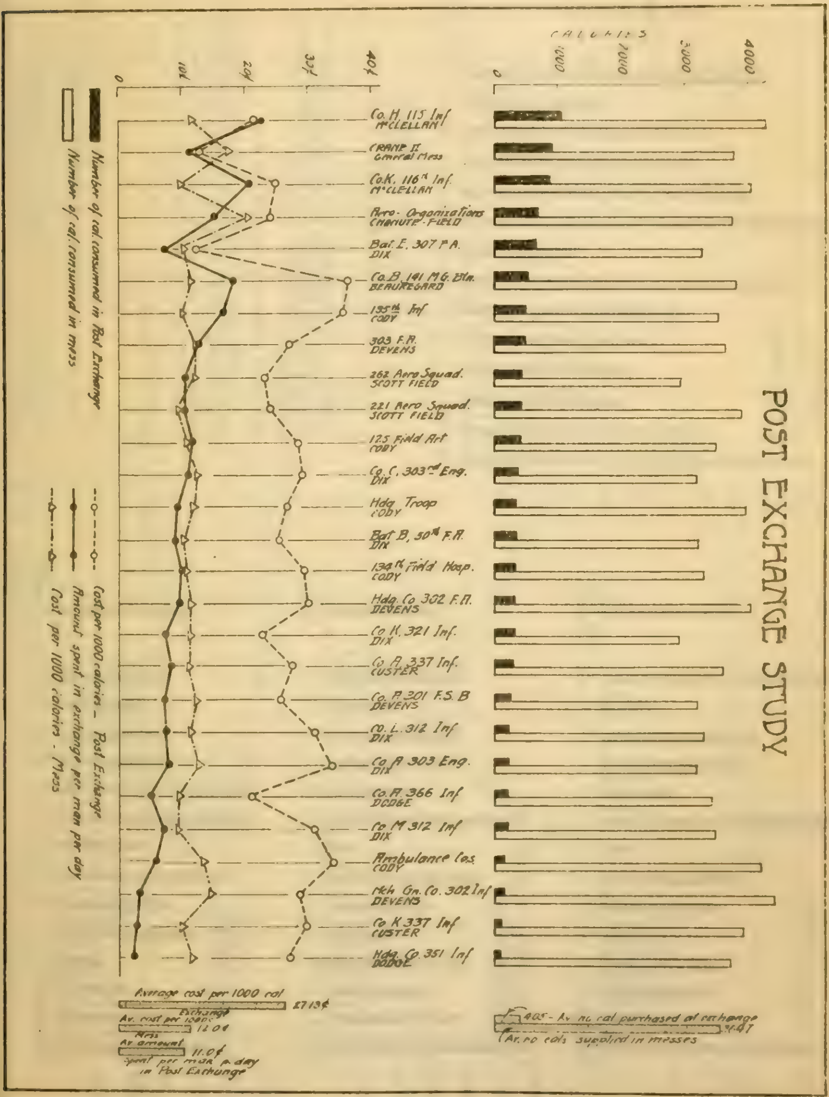

CHART No. 71.

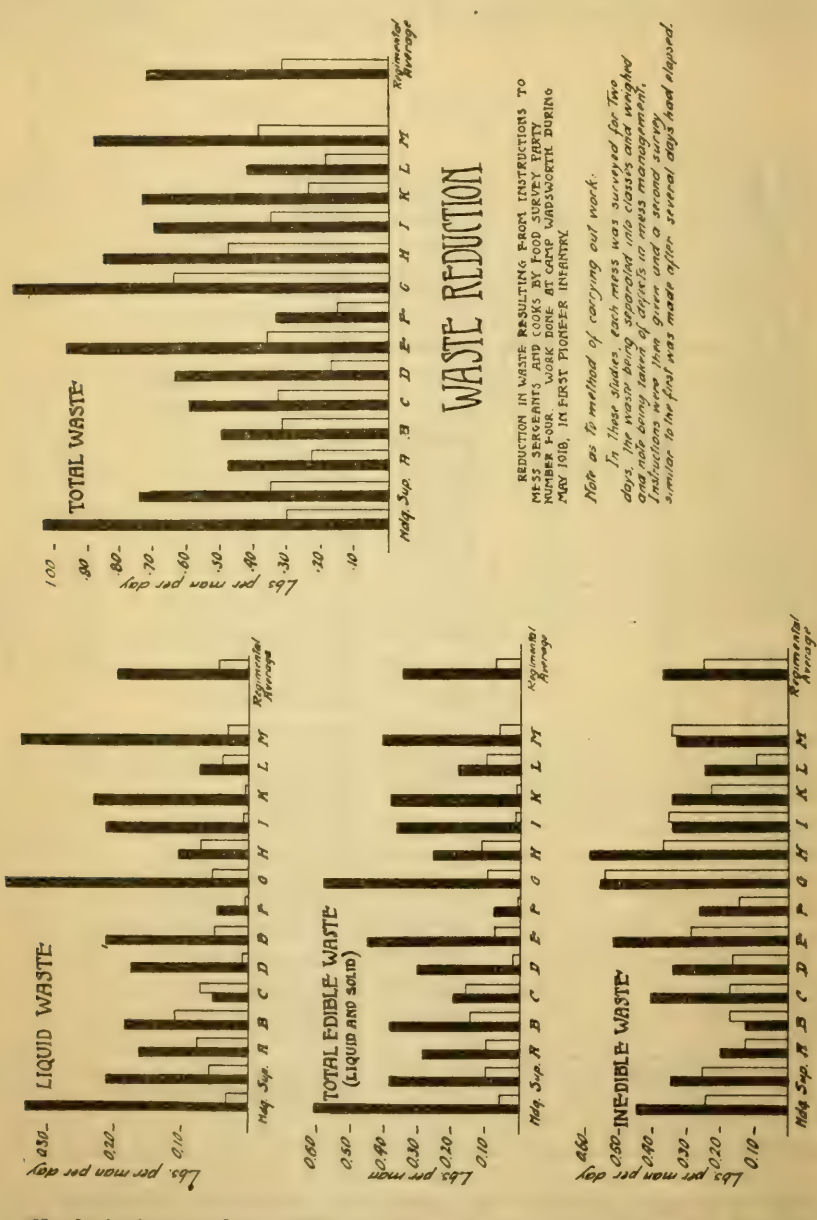
the tastes of the men as expressed in these average amounts actually selected, and that this modified ration be called the training ration to be used in the training camps of the United States.



WASTE REDUCTION

REDUCTION IN WASTE RESULTING FROM INSTRUCTIONS TO MESS SERGEANTS AND COOKS BY FOOD SURVEY PARTY NUMBER FOUR. WORK DONE AT CAMP WADSWORTH DURING MAY 1918, IN FIRST PIONEER INFANTRY.

Note as to method of carrying out work:

In these studies, each mess was surveyed for two days, the waste being separated into classes and weighed and note being taken of defects in mess management. Instructions were then given and a second survey similar to the first was made after several days had elapsed.

CHART No. 72.

Early in September, 1917, a request was received from the American Red Cross for a ration to be purchased by the Red Cross and supplied through the International Red Cross to American prisoners in Ger-

many. This ration is shown in Table No. 158. Likewise a request from the same source was received for a ration designed especially for American prisoners ill in enemy camps. This ration is shown in Table No. 159. Both these rations are now being supplied through Red Cross channels to American prisoners. A system of checking by receipts from individual soldiers furnishes satisfactory evidence that the rations are actually delivered.

With this war have come many new feeding problems. Much light is thrown on some of them by statistical surveys in the camps, but others call for special laboratory studies. Subjects which have been specially investigated by members of the Food Division are as follows:

(1) Dehydrated vegetables.
(2) Meat inspection and spoilage.
(3) The physicochemical properties of gluten.
(4) Relation of diet to specific muscular strength.
(5) Relation of diet to disease.
(6) New analyses of meat.

XIV. PERSONNEL DIVISION.

The Medical Department, like all other departments of the Army, has grown during the past year at an unprecedented rate. The increase has naturally been most marked in the Medical Reserve Corps. Thousands of physicians and surgeons in civil practice, inspired by a desire to be of service in the present emergency, have applied for and accepted commissions in the Medical Reserve Corps.

According to the Surgeon General's report of June, 1917, there were on June 30, 1916, in active service, 443 officers of the Medica Corps, and 146 officers of the Medical Reserve Corps.

On June 30, 1917, two and a half months after war was declared there were in the Medical Corps, 489 officers on active duty, an increase of 10⅓ per cent, and 3,636 officers of the Medical Reserve Corps on active duty, an increase of 2,390 per cent.

On June 30, 1918, there were in the Medical Corps, in active service, 867 medical officers, an increase of 81 per cent over 1917, and o 95 per cent over 1916. On the same date, there were in the Medica

Reserve Corps, in active service, 20,855 medical officers, an increase of 416 per cent over 1917 and 14,284 per cent over 1916.

There were in the United States in 1916, 146,332 physicians, so with 20,855 officers of the Medical Reserve Corps in active service, there are in the first 15 months after declaration of war, 14.65 per cent of the entire civilian medical profession of the United States on active duty as medical officers of the Army. This showing is most gratifying as indicating the disposition on the part of the civil medical profession of supplying whatever number of medical officers may be needed for the protection of the health and well-being of the American soldiers.

The following tables show the strength at different periods during the fiscal year from June 30, 1917, to June 30, 1918, of the Regular Medical Corps; Medical Reserve Corps; Medical Corps, National Guard; Medical Corps, National Army; the Regular Dental Corps; Dental Corps, National Guard; Veterinary Corps; the Sanitary Corps; and the Nurses Army Corps:

TABLE No. 160.—*Strength of the personnel, commissioned, enlisted, and otherwise, of the Medical Department on June 30, 1917.*

TABLE No. 180.—*Enlisted personnel, Veterinary Corps, by months, June 30, 1917, to June 30, 1918.*

Date.	Number.	Date.	Number.
Nov. 30, 1917	324	Mar. 31, 1918	5,946
Dec. 31, 1917	1,265	Apr. 30, 1918	7,720
Jan. 31, 1918	3,063	May 30, 1918	8,806
Feb. 28, 1918	4,268	June 31, 1918	9,383

The following shows the number of civilian employees at the Surgeon General's office, by months, from June 30, 1917, to June 30, 1918:

Date.	Number.	Date.	Number.
June 30, 1917	364	Jan. 31, 1918	739
July 31, 1917	438	Feb. 28, 1918	804
Aug. 31, 1917	438	Mar. 31, 1918	884
Sept. 30, 1917	524	Apr. 30, 1918	984
Oct. 31, 1917	546	May 31, 1918	1,093
Nov. 30, 1917	601	June 30, 1918	1,154
Dec. 31, 1917	673		

XV. DIVISION OF PHYSICAL RECONSTRUCTION.

This division (special hospitals and physical reconstruction) is separate from but coordinate with the hospital division. Its work is conducted through four sections, namely: Special hospital sites, buildings, and grounds; special surgical and medical reconstruction plans, that is, development of coordinate measures for continued treatment where necessary; therapeutic use of work and other physical remedies; and information and literature.

The section for special hospital sites, buildings, and grounds assists in the selection of sites for hospitals, the designing of buildings where needed, examination of existing buildings for hospital purposes, and necessary alterations, means for the therapeutic use of work, developement of special hospital equipment, including that required for physical therapy. Personnel: Architects, medical officers detailed as required.

Section of special surgical and medical reconstruction is in charge of development of plans for the necessary special treatment of the blind, deaf, and speech-defect cases, and of various other special conditions requiring special plans. It assists various professional divisions in preparing for special features of their work. This section is operated by representatives of the divisions of head surgery, surgery, orthopedics, neurology and psychiatry, internal medicine, and genitourinary. The section devoted directly to therapeutic use of work assists in the development of plans for curative shops and laboratories. This section acts as advisers in the selection of the proper application of work in so far as the medical requirements permit, with a view to future vocation; investigation of occupational possibilities for handicapped men; also assists in the study being made by the medical officers of this division in studying the use of handicapped men in the military service. The work of this section is performed by technical advisers in occupations as applied to the treatment of sick and wounded.

The section of information and literature has charge of the analysis of reconstruction literature; educational propaganda; study of existing literature on reconstruction and kindred subjects for the information of all officers interested; the preparation of monographs for offices; and the dissemination of information concerning the reconstruction work to the public so that a sympathetic attitude will be created which will aid materially in the success of treatment.

The establishment of reconstruction activities in hospitals designated for the work of rehabilitation was preceded by much preliminary work. A large number of buildings were inspected, and locations all over the country examined as to their desirability or otherwise for the work of medicomilitary refitting.

Having in mind, also, the necessary contact of the Surgeon General's Office with the civil agents and agencies required for the vocational training, placement, and follow-up of the disabled soldier, experts were detailed to make a study of the country's industrial plants, to determine whether these might be utilized for the reconstruction activities of both existing and proposed hospitals.

Similar surveys were made of technical schools and other institutions of learning for the purpose of determining the extent to which these might be employed for both vocational and prevocational purposes.

At the request of the Secretary of War the Surgeon General of the Army called a conference of a number of governmental and civilian organizations interested in the problems of reconstruction and rehabilitation of the disabled soldiers, with the idea of arriving at the best means of administering this work in all its ramifications. The conference met in the Surgeon General's Office on Monday, January 4, 1918. As the result of the conference a committee of 15 was appointed to prepare a report with recommendations.

As a result of the work of the committee in the conference a report was finally submitted to the Secretary of War along with a tentative draft of a proposed bill. This report outlined the functions of the Medical Department of the Army and the functions of civilian agencies in carrying on the work of physical reconstruction and rehabilitation.

The tentative draft of the bill was sent to the Secretary of War but was never introduced into Congress. However, as a result of this conference a bill embracing these same principles and giving the control of the work after the soldier was discharged to the Federal Board for Vocational Education, was introduced into the Senate by Senator Hoke Smith on March 9, and into the House of Representatives by Representative Sears on March 12.

The Secretary of War approved the following policy for the physical reconstruction of disabled soldiers:

> (*a*) That hereafter no member of the military service disabled in line of duty, even though not expected to return to duty, will be discharged from service until he has attained complete recovery or as complete recovery as it is to be expected that he will attain when the nature of his diasbility is considered. The inauguration of this continued treatment will result, during the period of the war, in the saving to the service of a large number of efficient officers and soldiers who without it would never become able to perform duty.
>
> (*b*) Physical reconstruction may be defined as the completest form of medical and surgical treatment carried to the point where maximum functional restoration, mental and physical, has been secured. To secure this result the use of work, mental and

manual, will be required during the convalescent period. This therapeutic measure, in addition to aiding greatly in shortening the convalescent period, retains or arouses mental activities, preventing "hospitalization," and enables the patient to be returned to service or civil life with the full realization that he can work in his handicapped state, and with habits of industry much encouraged if not firmly formed.

Recommendations of the office of the Surgeon General concerning physical reconstruction were approved by the Secretary of War on the 6th day of May, 1918, in the following language:

> You are authorized to proceed with the scheme for reconstruction of officers and enlisted men of the Army alone without consideration of the other bureaus of the Government involved. This reconstruction to be clearly understood to end at the point where the medical reconstruction ceases, that is, the reconstruction to take place in such cases of officers and enlisted men as come under proper medical treatment by the War Department, leaving for other reconstruction purposes the subsequent treatment after discharge from the care of the Medical Department.

On May 10, 1918, arrangements were made with the Bureau of Medicine and Surgery, Department of Navy, whereby the Surgeon General was given charge of such sailors and marines as require or may in the future require physical reconstruction.

The Surgeon General of the Army has (June, 1918) assigned the following general hospitals for the reconstruction of disabled soldiers and sailors, both from overseas and from training camps in the United States:

Disability.	Hospitals.
Insane	St. Elizabeths Hospital, Washington, D. C.; Genera Hospital No. 4, Fort Porter, N. Y.
Functional neuroses (nervous diseases)	Plattsburg Barracks, N. Y., Fort Des Moines, Iowa.
Epileptics	Plattsburg Barracks, N. Y.
Pulmonary tuberculosis	Fort Bayard, N. Mex. General Hospital No. 16, New Haven, Conn.; General Hospital No. 17, Markleton, Pa.; United States Hospital, Waynesville, N. C.; General Hospital No. 8, Otisville, N. Y.
Cardiovascular diseases	General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 9, Lakewood, N. J.; Fort Des Moines, Iowa; Corpus Christi, Tex.
Chronic rheumatism	General Hospitals Nos. 6 and 9, Fort Des Moines, Iowa.
Disabilities due to being gassed	General Hospital No. 2, Fort McHenry, Md.
Other general medical cases	Corpus Christi, Tex., General Hospitals Nos. 6 and 9; Walter Reed General Hospital, Washington, D. C. Fort Des Moines, Iowa.
General medical and surgical cases	General Hospital No. 3, Colonia, N. J.
Those requiring orthopedic treatment	General Hospitals Nos 6 and 9, Walter Reed General Hospital, Letterman General Hospital.
Amputations	Walter Reed General Hospital, Washington, D. C. Letterman General Hospital, San Francisco, Cal.
Total deafness, speech defects, and purulent otitis media.	General Hospital No. 11, Cape May, N. J.
Blindness or near blindness	General Hospital No. 7, Roland Park, Baltimore, Md.
Venereal diseases and its sequelæ (where venereal disease is major disability).	General Hospital No. 5, Fort Ontario, N. Y.
Wounds and injuries and other surgical conditions of the genitourinary system (where the injury or wound is major disability).	General Hospitals Nos. 2, 6, and 9; Walter Reed General Hospital, Washington, D. C.; General Hospital No. 2, Fort McHenry, Md.; Letterman General Hospital, San Francisco, Cal.; Corpus Christi, Tex.
Wound or injuries involving the head, including eye, ear, nose, and throat, face and jaw.	General Hospital No. 11, Cape May, N. J.
Special service of diabetes	General Hospital No. 9, Lakewood, N. J.; Fort Des Moines, Iowa; Letterman General Hospital, San Francisco, Cal.

The partial or complete personnel and the full minimum equipment necessary for curative occupation is in active operation at General Hospitals Nos. 2, 6, 9, 11, 17, and Walter Reed.

Staffs for the aforementioned general hospitals to care for the sick and wounded have been assigned from the professional divisions of the Surgeon General's Office.

As rapidly as conditions permit reconstruction work at all of the hospitals named is being developed.

At New York and Newport News, the ports of debarkation, the necessary organizations for the classification and rapid distribution of the disabled men from overseas to the reconstruction hospitals has been completed and is in satisfactory working condition. Division surgeons have been ordered to report the individual cases of disability who may be reconstructed now in the base hospitals of cantonments, that they may be transferred to the general hospitals where reconstruction work is carried on.

One feature of reconstruction which merits especial mention is that of artificial appliances. The artificial-limb problem has already at the time of our entrance into the war become a serious one abroad; the supply was far short of meeting the demand, and in many particulars the substitute failed to permit the restoration of function of the lost member to the degree that it seemed reasonable to expect. It appeared wise, therefore, to study the problem as exhaustively as possible. Accordingly one member of the division of military orthopedic surgery was assigned to this work and the division of physical reconstruction turned over to him the questions of equipment and supply in which it was interested. Further, the Surgeon General authorized the establishment of a laboratory for investigation and experimentation along the lines of artificial limb construction. The proper understanding of the problem necessitated its study from the standpoint of the amputation, the construction of the artificial limb, and the occupational demand to be made upon the substitute.

The subject of amputation had to be studied from the viewpoint both of the surgeon and of the artificial-limb maker. Accordingly the literature was carefully reviewed and a questionaire sent out to the artificial limb manufactures of the United States. The results of this study were embodied in an article on "The Relation between Amputation and the Fitting of the Artificial Limb" and reprints have been distributed to the surgeons of the Army.

The experience in Europe has shown the value of the temporary appliance. The most useful of these has proven to be the plaster peg leg, which, if desired can be supplied with an articulation for the knee. It is accordingly planned to use this for the earliest period, applying it when the wound is healed or nearly healed. A detailed description of the manner of making this appliance as well as a similar appliance for the arm, was also published in the Military Surgeon and reprints of the article distributed. Such a temporary plaster leg may be worn for a long period, even as long as six months, new sockets being made as the stump shrinks.

There are, however, many advantages in having the patient begin, as early as possible, to use an appliance similar in type to the regular artificial limb, as he is thus prevented from acquiring bad habits of walking, learns something of what modern artificial limbs will really do (thus being able to make a more intelligent choice of a permanent leg), and the fitting of the permanent leg can be delayed for as long a time as may be required, either by the condition of the stump, or the difficulty of manufacture. A simple artificial limb of this type, which is adjustable both for length of leg and size of stump, is now being thoroughly tested out in order to determine its value. Should this plan prove feasible, it will enable the amputated soldier to resume his work at a much earlier date than is usual in such cases, and will help very materially to solve the problem in case the number of our amputations should be very great.

The problem of the artificial arm is being studied, particularly from the standpoint of the requirements of the one-armed; attention is being given also to the needs of the individual occupation. The attempt is being made similarly to provide some form of temporary appliance which will satisfactorily meet the demands of the first six months. It is now believed that a satisfactory model has been devised.

Considerable progress has already been made also in the adaption of manual occupations and of games to the different types of amputation. It is believed to be of especial importance that the amputated, particularly those who have lost arms, be retrained to play. Hence this feature of the work of reconstruction is being given intensive study.

In these and other respects, therefore, the division has been making preparations thoroughly to fit itself for carrying out the treatment of soldiers and sailors suffering from disabilities of the arms and legs, when they shall be returned to this country.

On March 1, 1918, an officer was designated by the Surgeon General to direct the work connected with the education of the deaf soldiers and sailors and those with speech defects. On March 4, 1918, he was relieved from duty in the section of otolaryngology, surgery of the head.

At the present date there are available for teaching purposes 70 teachers without restrictions, and 46 teachers with certain individual restrictions. By a similar method 37 teachers have been obtained for corrective speech work.

Considerable difficulty was encountered in obtaining the proper institute in which the work was to be started, which has resulted in considerable delay in the practical part of the enterprise. First a hotel, the Mount Holly Inn, in Baltimore, was offered. Delay resulted in the lease being withdrawn. Efforts to reopen the lease after it had been accepted by the General Staff failed to accomplish its purpose. As a result of this failure the hospital division designated General Hospital No. 11, Cape May, N. J., as the temporary location for the section of defects of hearing and speech. This was authorized April 23, 1918.

On September 29, 1917, an officer was assigned to the division of physical reconstruction and special hospitals. The official assignment read, "as a representative of the section of surgery of the head." This officer was then directed to prepare plans, first for professional education of "returned" handicapped soldiers; second, plans for "reconstruction aides."

On October 15, 1918, he was relieved of these duties and definitely assigned to prepare plans for the reeducation of blind and deaf soldiers. On or about November 15 he procured a splendid tract of land with two large dwellings as a plant in which to conduct the teaching of the blind. On November 15 he located a place in Baltimore—Mount Holly Inn Hotel—which provided ample buildings and grounds for the teaching of the deaf. The former was accepted at $1 a year; the latter was only accepted after the offer had been withdrawn.

On October 15, 1917, he called to Washington 10 of the leading workers for the blind in the United States. To them was submitted, for criticism and correction, a plan for the reeducation of blinded soldiers. They formally recommended the adoption of corrected plans on October 17. The Surgeon General gave them his official sanction on October 19. Since that time he has been fully occupied in their development. This has required workers to go abroad, a director of teaching, and all the subordinate teachers for the new school, General Hospital No. 7, Baltimore, Md. Through the architects drawings for barracks for the military detachments, schools, swimming pool and gymnasium, manual training, recreation, etc., were made for General Hospital No. 7. An appropriation to cover the expense of this building program was procured and the buildings are now 98 per cent completed. An appropriation for the equipment of the buildings was procured and the equipment has all been ordered and 20 per cent received.

A survey has been made of all the blind shops in this country. The survey has been statistically recorded. A survey of 2,000 successful blind men was made to determine the subjects to be taught returned soldiers, so that the teaching might result in the replacement of the blind in wage-earning occupations.

Hundreds of autobiographical sketches have been asked for and received from the blind. The purpose of these is to enable us better to avoid the pitfalls which encircle the blind.

On June 8, 1918, the Surgeon General requested the American Red Cross to organize the Red Cross Institute for the Blind. This institute is to have the social and economic supervision over the discharged soldier. Just before this was accomplished an agreement was reached by which General Hospital No. 7 would serve the Navy—sailors and marines—as well as the Army. The Red Cross institute has added to its duties sailors and marines. At the request of the American Red Cross the Surgeon General assigned an officer as director of the institute in addition to his regular duties.

The subdivision of education was begun in October, 1917. The fall and winter (1917) months were occupied by the members of the division in the study of the educational work being done for disabled soldiers in Canada and European countries through reports, publications, and conferences with vocational officers and medical officers from some of these countries. They made also an investigation of various industries in relation to the possibility of employing disabled men. Also information was collected from several thousand cripples in the United States relative to their occupations, so that it would be known what can be done best by men with various types of disabilities. Plans were made for educational work in the hospitals and for the further reeducation of those injured, so that they would be able to enter their previous occupations or some other suitable gainful occupation. These plans were included in Senate Document No. 173, being a letter from the Secretary of War, transmitted in response to a Senate resolution of January 3, 1918, "A report of the Surgeon General of the Army on the rehabilitation and vocational reeducation of crippled soldiers and sailors." The plans followed at present in the educational work of the hospital follow closely those outlined in this printed document.

Vocational work was started in General Hospital No. 2, Fort McHenry, Md., early in March, 1918, under the immediate supervision of Maj. Henderson. There were in the hospital at that time between four and five hundred patients, approximately 200 of whom were over-seas men. Two or three volunteer teachers and several of the returned patients were used as instructors. Basketry, typewriting, telegraphy, and academic work were the first subjects of instruction. Early in April the larger number of patients in the hospital were distributed to other hospitals, breaking up practically the educational work started. As rapidly as new patients were received work was started again. At the present time (June 25, 1918) approximately 11 instructors and 250 patients are engaged in educational work. Instruction is given in academic subjects, including reading and writing to illiterates and others unable to read or write in the English language, and further general education to others who left school early in their career; also in stenography, typewriting, telegraphy, automobile driving, automobile repairing, motor mechanics, drafting, barbering, shoemaking, carpentry, basketry, chair caning, printing, tailoring, and cabinetmaking. The buildings authorized for the educational department have not yet been erected, but any available space, wherever it can be obtained, is being used.

Instruction at Walter Reed General Hospital covers practically the same subjects as at Fort McHenry. A department of oriental-rug repair work has been added. A total of 25 instructors is engaged in the educational work, and approximately 300 men are taking instruction. In addition to this, 16 women are employed as occupational aids, under the chief of the educational service. An old two-story residence on the hospital grounds is used for curative workshops and for headquarters for the educational officers. New buildings are under way to house the entire educational and curative workshop program. A greenhouse and 12 acres of land, loaned at no expense to the hospital, is used for instruction in gardening.

Equipment at General Hospital No. 9, Lakewood, N. J., is in many ways more satisfactory. A building adjacent to the hospital, formerly used for an indoor tennis court, 44 by 88 feet, is now used for the workshop. In this building are a carpenter shop, machine shop, shoe-repairing shop, printing shop, and automobile-repair shop. An inclosed veranda of the hospital building, 12 feet wide and 100 feet long, is used for academic classes, typewriting, telegraphy, drafting, etc. The chief of the educational service is Mr. Fred P. Reagle, vocational supervisor of the schools of Montclair, N. J. Assisting him are 17 instructors. A unique feature of the equipment is a linotype machine, loaned for the duration of the war by the Mergenthaler Co., on which a few men are being taught linotype operating. A plumbing shop for taking care of the plumbing in the building, an electric-light plant and repair shop, a steam laundry, a bakery, and a barber shop are all used in connection with the educational work.

Work at Fort McPherson, Ga., was begun under the direction of John E. Riley, formerly superintendent of schools, Holyoke, Mass., on April 15, 1918. A month later classes had been organized in 14 subjects, as follows: Motor mechanics, telegraphy, wireless telegraphy, typewriting, mechanical drafting, cabinetmaking, carpentry, harness repairing, poultry raising, shoe repairing, reading and writing English, penmanship and bookkeeping, printing, and newspaper reporting and editing. In addition, a limited number of patients were receiving training in trades or occupations in the post repair shops under the direction of the foreman of the shops, as follows: Tin repairing (sheet metal work), plumbing, stove repairing, steam fitting, blacksmithing, electric wiring, painting (interior, signs, wagons, autos), tailoring (repairing, pressing, cleaning, etc.), barbering, baking; gardening and agriculture have just been added. Approximately 150 men are taking courses; 11 men are used as instructors.

In General Hospital No. 17, Markleton, Pa., work was begun May 27, 1918. But few courses are offered at present, as this hospital is largely for tuberculosis patients, and it has not yet been determined what work can best be given them. Six instructors have been inducted for the work. Woodworking and gardening are the two principal occupations.

In addition to the above hospitals, a staff for educational work has been secured for General Hospital No. 3, Colonia, N. J., General Hospital No. 15, Corpus Christi, Tex., General Hospital No. 16, New Haven, Conn., Letterman General Hospital, San Francisco, Cal., and base hospital, Fort Des Moines, Iowa.

Instructors are commissioned officers, enlisted men, or civilians. The General Staff, May 15, 1918, authorized the commissioning of 1 major, 3 captains, 10 first lieutenants, and 10 second lieutenants as educational officers of the hospitals. On June 22 the War Department, with the permission of the Civil Service Commission, authorized the appointment of 24 curative workshop instructors as civilians, at salaries ranging from $1,800 to $3,000 a year. The instructors inducted into the service have been class 1-A men, or draft men classified for limited service, who were found qualified and who had had successful experience in educational work or in technical work. Disabled men returned from overseas are being used for instructors as much as possible. Men with technical training without experience in teaching have been given teaching work under the supervision of the chief educational officer. When cured and ready for discharge, those whose services were especially desirable have been transferred into the Medical Department and retained as instructors.

The organization known as reconstruction aides was transferred from the division of orthopedic surgery to the division of physical reconstruction on or about April 1, 1918. At that time this organization consisted of women trained in two different ways: (1) Those trained in physical education with a special knowledge of physiotherapy, ready to do the work of massage and other forms of physiotherapy; (2) women trained in crafts, for the purpose of teaching these crafts in the wards to patients who are not able to go into the shop for curative work. Many aides have been assigned to work in Walter Reed and other hospitals in which reconstruction is being carried on.

At first no allowance for quarters was made. Therefore, from February to May 18, 1918, these women received no allowance for quarters and did not begin to receive their pay, owing to the lack of necessary machinery, until April. The Red Cross, on June 24, satisfactorily made up the deficit in each individual case. At present reconstruction aides receive $50 pay ($60 overseas), with quarter and subsistence.

On April 13 to 27, 1918, an exhibit of handcraft work was held i the Surgeon General's office. A week later an exhibit of work wa held at the handcraft guild as part of their general annual exhibit The Smithsonian Institution stated that they would be glad to hav an exhibit some of this work done by the men in the hospitals.

On December 27, 1917, an officer was assigned to duty of providin such literary material, translations, reviews, abstracts for official and others, especially in the services of special hospitals and reconstruction, most likely to assist in carrying on the special work.

A list of monographs, articles, etc., in Italian, French, English and German on the general subject of reconstruction and reeducatio of disabled soldiers and sailors was begun. Abstracts from materia sent by courtesy of the Canadian Military Hospital Commission hav been made.

Preparation of abstracts of work done in most foreign countries on reconstruction hospitals and vocational schools, containing lists o books and articles in all languages on the general subject, has bee continuously carried to date.

In January, 1918, an arrangement was made with the librarian o the Surgeon General's library to allow a representative of thi division to occupy daily a desk in his building half a day for th purpose of research; also to have the assistance of Col. Owen i preparing photographs and other reproductions of maps, plans, etc. for this work. Four mimeographed and illustrated bulletins, giving a complete account of rehabilitation of the soldier in all the belligeren countries doing extensive work of this kind, have been published and issued chiefly to medical officers of the Army. These bulletins were discontinued in June, 1918, and their place taken by Carry On a monthly magazine edited by a board created by the Surgeon General.

Since educational propaganda of a proper and wisely controlle character is generally regarded as essential to a clear understandin of reconstruction work by the public and by the various agencie necessary for its success, in addition to the use of the bulletins firs mentioned and the magazine, Carry On, many lectures and addresse dealing with the subject have been given in various towns and citie by officers of this division assigned for the purpose. The chie instance of public education and propaganda is the meeting of the American Medical Association in Chicago on June 13, 1918, when an entire day was given over to the reading and the discussion (in the miscellaneous section) of papers on the whole subject of physical and vocational reconstruction of the disabled soldier and sailor by officer of this division and others. Col. Billings was chairman of the section the sessions being held in the Auditorium, which was crowded by mixed audience of members of the association and the public.

This propaganda, so vital to the creation of a healthy public sentiment, is now being carried on through all the usual channels o publicity—magazines, newspapers, moving pictures, addresses befor medical and other societies, and by means of a wider publicity secured by the (unlimited) use by newspapers of the contributions t Carry On. In this connection it may be said that the initial issu

250,000 copies) of this magazine included 25,000 names and addresses f Army and Navy medical officers, dentists, and Army nurses, and hat this part of the mailing list will be permanent, while the mailing ist of future issues (of about 75,000 copies) will probably be varied rom time to time so as to reach as large and as widespread a contituency as possible.

XVI. Division of Medical Department Training.

The training scheme of the Medical Department for the war with Germany had its foundation in the field service and correspondence chool for medical officers, Army service schools, Fort Leavenworth, Kans. This medical officers' school was established in 1912. Its purpose was to develop and standardize a scheme of training for medical officers such as had not previously been given. Up to the outbreak of the war with Germany it had annually graduated classes of medical officers of the Regular Army and Organized Militia, and conducted extensive correspondence courses with a large number of Regular and Reserve Corps medical officers. This school developed the nucleus of men who were later to make possible a broader raining on the Mexican border and throughout the Army and Organized Militia.

A second and more elaborate scheme of training, to include not only officers but enlisted men, was carried out on the Mexican border in 916–17 by the Regular and militia troops there mobilized, under a comprehensive plan, approved by the commanding general Southern Department, and issued on August 4, 1916, as "Memorandum on nstruction of medical officers and sanitary units." Under this memorandum the training of medical officers and enlisted men of the Medical Department was prescribed, standardized, and enforced. t gave many a basis information which they were shortly to be called upon to use on a vast scale in the training of a mass of newcomers into an immensely expanded Medical Department. The great value of this border scheme of instruction in carrying out the final great Medical Department war training can scarcely be overstimated. Through it a considerable number of more or less ualified instructors were created and the best type of training necessary to meet needs became apparent.

Hence, when the final need for training suddenly developed, the Medical Department was in a way prepared to meet it. On the day hat the United States declared war on Germany a letter urging the mmediate necessity of instituting measures for the training of Medical Department personnel was submitted to the Surgeon General.

The necessary plan for its practical execution was prepared after onference with the Bureau of Militia Affairs, which had just prepared short course of armory training for the medical department of the Organized Militia.

This report and plan was, on April 21, 1917, forwarded by the Surgeon General to The Adjutant General, with the following remarks:

> 1. The attached scheme affords a plan for starting, without delay, the necessary aining of the officers and men of the Medical Department. It can be modified later experience may warrant. It proposes to carry out an intensive training of both ficers and enlisted men, both in special training camps and in addition to necessary rvice with troops. For the former class, the course covers three months; for the tter, six months.

2. The nature and scope of the proposed course, sample of daily routine, list of textbooks, etc., are given therein.

3. For the above instruction purposes, it is believed that four medical training camps should be established. The Medical Department, among other cogent reasons, can not furnish instructors or equipment for more than this number. They should be established in conjunction with the general officers' training camps at Fort Oglethorpe, Fort Riley, Leon Springs, and Fort Benjamin Harrison, and later, if found desirable, one on the Pacific coast; but if a suitable camp and maneuver ground can be found on the Atlantic seaboard south of New York, this should be substituted for Fort Benjamin Harrison.

4. If approved, I recommend that the necessary facilities for shelter, messing, supply, etc., be provided without delay for the use of these training camps at the above points.

5. Authority is also requested for the bringing to these training camps of a training staff of approximately one officer instructor to each fifty (50) student officers, together with such enlisted personnel as may be necessary.

6. I also request that one ambulance company and one field hospital be sent to each of these training camps, and that three additional ambulance companies and three additional field hospitals be organized at each without delay. Also that each training camp be further provided with an enlisted force equivalent to six regimental sanitary detachments. The above personnel is necessary to visualize medical organizations, equipment, and fieldwork, and serve as a service corps in looking after the training camp and the many hundreds of student officers to be in attendance.

7. Authority is further requested for the establishment of a training course for the sanitary personnel with troops, the appointment of officers as training officers with divisions or separate camps, and the establishment of a system of inspection sufficient to insure the efficiency of the same.

8. It is requested that this matter be given decision as soon as possible. It is understood that the general training camps are to begin operation on May 15. The Medical Department should begin its work at least by that time, and if possible, one or more of its camps should be put into operation before that time.

9. Attention is invited to the fact that the work of the Medical Department actively begins the moment troops are raised or brought together, and that the equipment of these training camps, the detailed organizations of the training course, and the provision of the staff of instructors should therefore be made as soon as possible.

The plan was approved and acted on by the War Department as follows:

2581692 1st Ind.

War Dep't., A. G. O., May 11, 1917.

To the Surgeon General, with the information that the establishment of additional sub divisions of the work in the office of the Surgeon General, as referred to herein, is approved with the following exceptions:

That no increase in the Medical Corps in number or grades shall accrue therefrom;

That the chief of the sanitary section may consult with, and make recommendation to the Quartermaster General in regard to construction of a sanitary character, and may also recommend sanitary orders, but all orders will be issued in the way now prescribed by regulations; and

That four medical training camps, to begin June 1, 1917, with an attendance of officers for training at each to be not over 600, are approved; and that the tentative scheme of instruction is approved and will be submitted in form to be published as a general order.

It should here be mentioned that the proposed medical officers' training camp at Leon Springs, Tex., was never established, through inability to provide the necessary staff of instructors therefor. However, authority was later received to raise the quota of student medical officers from 600 to 1,000 at each of the other three camps, with the net result of an increase of 600 medical officers in all.

To each of these camps a training staff of selected regular medical officers, each one recognized as an expert in his line, was assigned. These staffs varied from 10 to 12 officers.

The work of instruction was at once started. As the first need for medical personnel was obviously to be with the regiments and divisions shortly to be organized, a course was worked out to meet such need for the zone of operations, and this still remains as the basic course of the training work. Later, courses for line of communications work, for special training in various medical branches, and courses for the several nonmedical branches of the Medical Department were organized.

The basic course of training to be carried out at these medical training camps was covered in a letter of instructions. It may here be remarked that this basic course has been found satisfactory, practically without change, after a year's practical trial.

The camps opened on June 1, although an effort was made to have orders for student officers amended so as to have them report on June 15. This effort for delay failed through clerical error in the War Department, and considerable numbers of student medical officers arrived at these camps on June 1, and thereafter. This, though regretted at the time, proved to be fortunate, as it gave an extra fortnight of much needed training to many.

What this training meant may be inferred from the fact that on August 27, 1917, one week before drafted men were to arrive at National Army divisional encampment, there left from each medical training camp five trains of medical officers and enlisted men of the Medical Department. Each train went to its separate camp and contained a quota of about 60 medical officers and 310 enlisted men, who were not only suitably organized for the formations with which they were to serve, but in each detachment officers and men were specially selected for fitness in the duties which they were intended to perform.

These 900 medical officers and 4,600 enlisted men went to the 15 divisions that were ready for them, and were able to provide for themselves, attend to sanitary matter, and arrange for handling of recruits in great numbers in advance of the arrival of the latter. By this means the Medical Department met the strain imposed upon it at the start, and it has since proved itself equal to all later emergencies by drawing from the trained reserve in the training camps.

It should be mentioned here that at this time a considerable number of physicians from civil life were entering the Army and were being sent direct to service with troops at posts and camps, without having the benefits of training given at a medical officers' training camp. It was realized that unless attention was drawn to their shortcomings, and a way prescribed for their remedy, that outside of the daily routine little, if anything, would be done in preparation for future and probably quite dissimilar duties.

Accordingly, a letter of instructions was sent to all department and Regular Army division surgeons similar to that given above as outlining the instruction at medical training camps. It was realized, however, that many of the facilities at the medical training camps would not be available at posts, garrisons, and small camps, and the course at such places was therefore appropriately modified. A full course of reading was everywhere prescribed, with such practical fieldwork as local facilities afforded. Commanders were charged enforcement of the requirements of the course, the Inspector General's Department being asked to specially check up this matter. On the whole, this garrison training has been very helpful and a vast amount of work has been done by untrained medical officers who, in the absence of such guidance, would neither have recognized its need nor the nature and manner of attempting it.

The next step of instruction was that for the training of medical personnel with divisions. On October 3, 1917, a letter of instructions was sent to all division surgeons, prescribing a course of training effective November 1 to be carried out as rapidly as local conditions permitted and to be concluded only when the Medical Department personnel had demonstrated reasonable qualification therein before a board of medical officers. The total ground to be covered approximated that included in the medical training camp course, and a ''training officer'' for each division was ordered designated. As each division contained officers and men who had practically completed the course at training camps, others who had only partially completed it, and still others who had not been trained at all, it will be realized that it was no easy task to give each individual the exact training necessary to remedy his deficiencies. However, this training has been well carried out and with excellent results. Divisions in which much sickness occurred during the winter, or in which there was a rapid rotation of recruits, suffered a proportionate delay in completing trainage.

After covering the prescribed course, and thereby securing the fundamental training of the great majority of medical personnel, no further medical training was officially required in divisions, it being believed that it could safely be left to division surgeons to require the proper training of such new medical officers and enlisted men as might require training after joining. Also it was believed that the prescribed course of training would furnish any necessary number of instructors for any later course of instruction.

In the late fall it became apparent that a certain proportion of medical officers who had gone direct from civil life into hospitals were not being qualified for their duties as rapidly as desired. The division of hospitals was requested to take steps to rectify this condition, which it did by the issuance of a letter dated November 3, and a memorandum in detail dated November 15. In both of these a course of study, training, exercises, clinics, etc., was prescribed.

It later became probable that a hostile propaganda furthered by an unthinking newspaper sensationalism would call the professional competency of Army medical officers into question. It was also apparent that a certain number of medical officers who were not giving satisfaction in their present duties were probably ''misfits'' rather than ''unfits'' and merely required assignment to a different kind of duty in order to render efficient service. Accordingly, letters on December 14 were sent out and put into operation. Under their provisions a certain number of medical officers were assigned to other duty, while a much smaller number were found to be professionally unfit and were discharged from the service. When the criticism which was apprehended finally developed, as it did six weeks or more later, the alleged deficiencies—never at any time actually of any great importance—had already ceased to exist as a result of this official readjustment and weeding out.

A large number of schools for the training of enlisted men in special work was early developed. These enlisted men's schools included those for the making of noncommissioned officers, nurses and ward men, dispensary assistants, surgical assistants, clerks, cooks, chauffeurs, and gas-engine mechanics. Classes of medical officers and enlisted men in automobile maintenance are also maintained at the Carnegie Institute, Pittsburgh, Pa.

These schools for enlisted men have performed a most valuable service and have turned out reasonably qualified men in great numbers along the above lines.

The medical training camps have also been required to organize, maintain, and supply a large number of practically every formation which the Medical Department provides. Some of these are permanently attached to the camps as training units: others are provisional organizations without official status but used for training purposes until needed for conversion into new official organizations. Still others are organized solely for the purpose of being sent away at an early or later date.

It will be at once apparent that the creation of sanitary organizations at medical training camps is tremendously facilitated by a sufficiency of trained supervising officers, an immense number of student officers from whom to select individuals possessing the special military and professional qualities called for, and by many thousands of enlisted men coming from every conceivable walk, profession, trade, and handicraft in civil life. An organization is thus built of carefully selected officers and men, each chosen for their ability to satisfy a certain specific need and perform a certain duty to best advantage. Misfits are avoided.

Besides the three training camps already mentioned, a similar camp was established at Fort Des Moines, Iowa, for the training of colored medical officers and colored enlisted men of the Medical Department. Its official capacity was 125 officers and 1,000 enlisted men, and it was in operation between July 21, 1917, and December 1, 1917, when the need for colored medical officers was satisfied. The training given in this camp was in regimental work only, as it was understood that colored sanitary personnel would habitually be attached to colored organizations.

Regarding the allowance of personnel for the Medical Department which was sent to camps for training, both in respect to officers and enlisted men, it may be stated that this has never been sufficient, as demonstrated by the fact that the services of the great majority thus sent to camps were so imperatively demanded outside as to cause their being ordered away before completion of their training course. There have been instances in which enlisted men have been sent away after arrival as soon as they could be equipped, and of medical officers who could be held for training, but two or three weeks. Despite every effort to create a fully trained reserve of officers and men, this has not been possible. The only "reserve" the Medical Department in this country has had has been the officers and men under training, and this training has been, and must be, considered as a secondary to meeting the actual needs of the Medical Department in caring for the sick and disabled.

There has been constantly a tremendous shortage in the enlisted personnel of the Medical Department, varying from one-fourth to one-third of the total number which should have been enrolled in its service to comply with existing standards of organization. This shortage in gross enrollment has seriously interfered not only with the number of enlisted men who could be trained in medical training camps but upon the length of time during which they could be allowed to remain under such training.

As to medical officers under training, their number has been sufficient to fill all drafts made on the medical training camps, but not sufficient to insure that officers so drafted would at all times be adequately trained.

The needs of the Medical Department require that 3,000 medical officers, 500 officers of the Dental Corps, Veterinary Corps, and Sanitary Corps, and 35,000 enlisted men of the Medical Department shall, as a minimum, be constantly under training.

Recognition must here be made to the wonderful spirit manifested by both officers and men in all these training camps, a psychical quality common to them all. It represented the spirit of service in its broadest and best sense, for many officers who responded to the call to the colors did so at great sacrifice. It was particularly this class of officers which had given up most which was most apt to make light of difficulties and ignore the discomforts incident to the establishment of these camps. All were imbued with a spirit of patriotism, and of loyal desire to make their profession and corps excel in the service of the Nation.

Discipline has been excellent and the need for punishment for military offenses rare. The camps have been governed not so much through the fear of court-martial as by the highly developed spirit of cooperation which has flourished in the student body, both commissioned and enlisted. There has been a pride in exemplary conduct and in the efficient performance of duty, which has largely rendered unnecessary any official pressure for the enforcement of orders.

Each camp has published a "year book," profusely illustrated with its camp scenes, which is an expression of camp enthusiasm and loyalty. The last of these books to be published, that of the camp at Fort Riley, is far larger and more elaborate than its predecessors from the other camps.

Besides facilitating the acquirement of necessary military information and training in the most effective and shortest way, these training camps have had a most profoundly beneficial effect on the mental attitude of the medical profession toward the military service. They have explained the reasons for many not always simple relations, and have proved a most useful bond of mutual understanding and good feeling between the regular medical officers and those of the Reserve Corps.

The camps also have done great things for the profession and country. They have produced thousands of excellent practical sanitarians who, after the war, will never countenance such sanitary faults as have been acquiesced in the past. They have taught the medical team work and the advantages of mutual utilization of special services among practitioners who heretofore regarded each other too much as business competitors. They have shown thousands how to organize and administer hospitals whereby, after the war, many a small community now thus unprovided will acquire its own. They have taught medical men not only how to be officers but to be better doctors and better citizens.

The system of Medical Department training has been of the greatest value in promoting the efficiency of that department. The system has reached into every part of the Army, sought out the medical personnel, and required the latter to benefit along common lines of instruction. The whole theory, outside the training camps, was, after the day's duty was done, to systematically learn in advance how to handle the dissimilar duties sure to come with future change of status and environment. In the much more intensive training of the medical training camps it is a safe estimate to say that upward of 10,000 medical officers and upward of 40,000 enlisted men of the Medical Department have, up to the date of signing this report, participated. From now on, until the war is over, it is desired that all medical officers and at least a major fraction of the enlisted medical personnel shall receive the medical camp training.

XVII. Dental Service.

1. ENROLLMENT OF DENTAL OFFICERS.

The records show when this Government entered the present war the American Army had 86 dental officers, 18 of whom were captains and the remainder first lieutenants, and although our dental law permitted dental officers to advance to the grade of major, this was only possible after said officer had a record of 24 years of service and limited the number to eight, regardless of how many there might be who had served the required 24 years. Of the 86 then on duty, only 55 were stationed in the United States, and these were widely scattered.

Although a law existed at this time which permitted the organization of a Dental Reserve Corps, no rules or regulations had been promulgated to organize such a corps until after we entered the present war. and although many dentists were eager to enter the Dental Reserve Corps, the early plan pursued made it necessary for an applicant to forward his request to the Surgeon General's office. The formal application was then furnished to be filled out and returned to Washington. The applicant was then communicated with and advised when the next board was to meet in his own State or an adjacent one, with the result that many days or weeks would elapse from the time the applicant would first apply until his completed papers would arrive for final decision. To prevent, if possible, this delay, the chairman of the committee on enrollment and legislation of the dental committee of the General Medical Board presented to the Surgeon General, on June 1, 1917, the plan whereby he was to be permitted to select representative men of the dental profession who, by education and experience, were well qualified to give professional examination to any applicant who desired to be commissioned in the Dental Reserve Corps. This request, although most unusual, was immediately accepted and authority granted. Twenty-four hours thereafter preliminary dental examiners were appointed in every State in the Union.

The men appointed as preliminary dental examiners were the deans of the well-recognized dental institutions, the secretary of each of the state dental examining boards, and such dentists in addition as the service demanded.

The end result of the appointment by the Surgeon General of the preliminary dental examiners is found in the fact that although on the day of its authorization, June 1, 1917, or relatively two months after the beginning of war, there were only five officers in the Dental Reserve Corps, yet we find on September 18, 1917, or three and one-half months thereafter, all examinations for general practitioners were discontinued, as the War Department had a sufficient number of commissioned dental officers and completed applications on file for action to care for the present and immediate future needs of the Army.

Since the declaration of war the number of dental officers in the Army has increased from 86 in the Dental Corps, Regular Army, to 212; National Guard, from nothing to 253; Dental Reserve Corps, from nothing to 5,372; making a total of 5,837, or a sufficient number to supply the quota now being assigned for an Army of 5,000,000, which gives to this nation a greater number of dental officers, subject to military call, than all nations combined represented by the term "The Allies."

The following two facts are considered worthy of being recorded: (1) The commission of first lieutenancy was tendered nearly 6,000 dentists, and all but 139 of these have accepted; (2) although the Dental Reserve Corps of the Army is authorized for its present strength to have 2,118 captains and 1,265 majors, there have only been 250 promoted to the grade of captain and 65 to the grade of major. This can be accounted for by the splendid plan that has been followed in regard to the question of promotion, for here we find that every dentist coming into the service must accept the grade of first lieutenant, and he can not be advanced until after being placed on active duty, and then only does he become eligible when he has been recommended by his superior officers through military channels.

2. DENTAL LEGISLATION.

On October 6, 1917, a dental law was enacted by the Senate and House of Representatives, in Congress assembled, and approved by the President, which gave to the Dental Corps of the Regular Army the same grades and percentages within the grades then allowed or that might thereafter be allowed by law for the Medical Corps of the Regular Army. This bill was referred by the Surgeon General to the Adjutant General of the Army for interpretation, and the decision was reached that under the present strength of the Army, the Dental Corps was authorized to have 9 colonels, 17 lieutenant colonels, and 67 majors, the remainder of the authorized strength of the corps to be distributed in the grades of captain and first lieutenant.

3. FREE DENTAL SERVICE.

On August 19, 1917, with the approval of the Surgeon General, permission was sought from the Provost Marshal General to secure franking privileges for the Preparedness League of American Dentists, and concurrence in a plan which would make it possible for all men who had been accepted for general military service to be advised to appear before the members of that organization to have any urgently needed dental operations performed, without expense to themselves or to the Government, previous to their arrival at camp. This work was considered imperative at that time, for the reason there was only being assigned one dentist per thousand of the total strength of the Army, and also the manufacturers were unable to meet the excessive demands made upon them in the early days of the war.

The Provost Marshal General heartily approved of the proposal made, and gave every assistance possible, even urging by personal letter the governor of each state to inform all local and medical advisory boards that he approved of their appointing a dentist for volunteer service on each board to aid in the physical examinations of all men called before them, and expressed it as his opinion that the patriotic service offered by the dental profession would be of great value not only for the comfort, but for the efficiency of the National Army.

Following the department's approval, a Dental Reserve Corps officer was assigned to the Preparedness League headquarters in New York, who, in cooperation with the officers of that organization, has increased in the past year from about 4,000 to 16,000, and as a concrete example of what the officers and members have contributed in the form of gratuitous service for men who have been accepted for general military service, it is here recorded that they have furnished the material and performed 375,000 gratuitous operations for men selected for general military service. It should also be stated that through their activity three dental motor car ambulances have been presented to the Government and another one is to be tendered in the immediate future.

4. SURGERY OF THE HEAD.

On June 15, 1917, the Surgeon General approved of the organization of the section of the surgery of the head, which had among other duties the securing of a personnel especially qualified to care for diseases and injuries of the brain, eye, ear, nose, and throat, face and jaws, and placed in charge a member of the Medical Corps, Regular Army. The commissioned personnel of the surgical head unit to consist of one specialist each for the brain, eye, ear, nose and throat, one plastic or oral surgeon, and one dental oral surgeon, competent to care for fractures, impactions, and pathologic diseases to which the teeth and jaws are subject.

It is believed by including dentists in the organization of the surgical head unit, better service will be given to our wounded soldiers who sustain injuries of the face and jaw than could possibly have resulted had these cases been handled without the assistance of those specially trained dental officers, and, in addition, a splendid opportunity is given to members of this profession to increase their ability and knowledge of surgical principles involved in the management of these surgical lesions.

5. EDUCATIONAL ACTIVITIES.

In May and June, 1917, a majority of the dental schools of this country instituted gratuitous courses of special instruction for applicants desiring to enroll in the Dental Reserve Corps. The course was approved by the Surgeon General, and was of such a nature as to fit those in attendance to be better officers for hospital and field service. The instruction embraced the relationship of the dental officers to the supply and administrative departments of the Army and military law. A number of the institutions have repeated these courses at various intervals, one of which had a total enrollment of 624. It is a conservative estimate to state that between four and five thousand dentists attended these courses of instruction without expense to themselves or to the Government, and the dental educational institutions of this country have a right to feel proud of this contribution.

On October 15, 1917, by authority of the Surgeon General and under the direction of the subsection of plastic and oral surgery of the surgical head unit, courses of instruction in plastic and oral surgery were instituted at Washington University Dental School, St. Louis, Mo., Northwestern University Dental School, Chicago, Ill., and Thomas W. Evans Museum and Dental Institute, School of Dentistry, University of Pennsylvania, where medical and dental officers were detailed for instruction. The medical officers were given special instruction in plastic surgery, blood transfusion, and bone transplantation, and the dental officers in bone fragment fixation by intro-oral splints, the systemic effects of focal infections, and surgical anatomy of the face, jaws, and neck. These courses were discontinued in March, 1918.

On March 15, 1918, a school for Army dental officers was instituted at Camp Greenleaf, Chickamauga Park, Fort Oglethorpe, Ga., in connection with the medical officers' training camp, for the military and professional instruction of dental officers and their authorized dental assistants.

The duration of the general course of instruction for the dental officers is two months. The first month is given over to 180 hours of general military training and the second to 70 hours of special military training, and 110 hours devoted to professional subjects that have a definite relation to general dental practice as it should be conducted in the Army. Each class consists of from 80 to 100, and a small percentage of each is retained for training to qualify them for assignment as division dental surgeons or assistants to the division dental surgeon. In the immediate future a few will be retained from each class for special instruction in Röntgenology, as we have need for two dental Röntgenologists for each cantonment in this country, as authorization has recently been received for the installation of complete radiographic equipment in the dental unit building in each camp.

In this officers' training camp we have dentists receiving military training that is of such a nature as will greatly increase their physical and professional efficiency. Furthermore, in so far as we know, this is the only country giving such extensive special training in military and professional subjects to dental officers and their authorized assistants.

XVIII. Division of Veterinary Corps.

The history of the Veterinary Corps dates from the approval of the national defense act, June 3, 1916. Section 16 of this act authorized veterinarians and assistant veterinarians. Assistant veterinarians were given the rank, pay, and allowances of second lieutenants for the first 5 years of service, and of first lieutenants from 5 to 15 years. They then become veterinarians with rank, pay, and allowances of captains until 20 years of service when they become majors. They were to be assigned to duty with mounted organizations as inspectors of horses and mules and as inspectors of meats, and constituted the Veterinary Corps which was specified as a part of the Medical Department. Veterinarians then in the service were authorized to be transferred to the new Veterinary Corps on passing the required examinations or if found physically disqualified to be retired. Such number of reserve veterinarians as were needed to attend animals in the quartermaster corrals were authorized; the same to constitute a list of eligibles for commissioned grades.

This legislation marked the culmination of the efforts of leading members of the profession in this country, both in and out of the Army, to obtain adequate recognition through the establishment of a commissioned status for Army veterinarians which had extended over a period of 32 years. Indeed few civilian veterinarians realized the importance of this step and the indifference and inability to agree on united action was for a long time reflected in the apathy of Congress.

For many years the veterinary service of the Army was rendered by civilians employed by the Quartermaster Department under contract. In 1900 the veterinarians attached to regiments of cavalry and field artillery were given the rank and pay of second lieutenant, without privilege of promotion or retirement, and still leaving a considerable number of civilians on duty at quartermaster corrals and depots. The service was never organized, no enlisted men were provided, and the professional standard of the veterinarians in many cases was low with neither opportunity nor hope for improvement.

Following the passage of the act of June, 1916, the Surgeon General inaugurated the work of establishing the corps. An examination board of three medical officers and two veterinarians was appointed. Owing to the necessity of securing interpretations of the law and the many scattered places of duty of veterinarians in Mexico and along the border, in China and in the Philippines, the work of conducting the examination was unavoidably delayed. Many of the veterinarians then in the service were lacking in the educational, professional and moral qualifications essential to a commissioned officer. A careful sifting of men necessarily followed.

On April 11, 1917, a total of 62 veterinarians had been found qualified and commissioned, further increased by July 1 of the same year, to 91.

The Veterinary Corps of the Regular Army, increased in proportion to the enlarged Army, numbers on the active list, at this writing, 118 officers.

1. DEVELOPMENT AT THE OUTBREAK OF THE WAR.

On April 14, 1917, the 62 officers of the Veterinary Corps of the Regular Army comprised the entire veterinary service. The entrance of this country into the war demanded an enormous increase in the Veterinary Corps as in every other branch of the service. Examinations were promptly held to fill the vacancies up to the authorized strength of 118. It was also necessary in the emergency to examine and commission reserve officers and call them to active duty to care for the large number of public animals about to be purchased and distributed to the auxiliary remount depots under construction at the cantonments throughout the country.

The plan adopted was to call on the deans of the recognized schools to give the professional examinations to desirable men between 20 and 55 years of age, after which the successful candidates were physically examined by a medical officer, and on qualifying were commissioned as second lieutenants, Veterinary Reserve Corps. It resulted in a large number of new officers in an emergency, and was undoubtedly the best plan available.

A committee appointed by the president of the American Veterinary Corps Association came to Washington and conferred with the Surgeon General on March 22, with regard to the expansion of the corps necessitated by the war, later with the medical advisory board of this office. In anticipation of the necessity for legislation to establish the Veterinary Corps of the National Army, much preliminary discussion and planning ensued to prepare for such legislation. A tentative organization was drawn up by these committees based on the British system. In July, 1917, after securing the Surgeon General's approval to the proposed organization, the committee called on the Secretary of War and was then informed that no special legislation was required, and that the Overman Act of May 18, 1917, give the President authority for expanding the Veterinary Corps organization during the present emergency.

A memorandum was prepared recommending that veterinary officers of the National Army be given rank up to colonel and that an enlisted personnel be provided. This recommendation, which was concurred in by the Surgeon General, was practically identical with the provisions of General Order No. 130, published later, except that it called for 3 colonels and 9 lieutenant colonels. It was presented to the Surgeon General about August 1, and the General Order was issued in October.

Veterinary officers.—The supply of officers had been very early the most urgent problem for the new corps. On September 30, 1917, it was apparent that more men had been examined than could be absorbed for several months, and all examinations were suspended, unfinished examination papers completed, and no further men from civil life have since been examined, except in two or three special cases where it appeared that an injustice would be done the applicant by refusing such examination. Seven hundred and ninety-seven officers on active duty and a waiting list of about 500 resulted from the examinations, and this list has been drawn on as required. It numbers 245 at present.

Besides civil life, officers have been drawn from two other sources, the National Guard and graduate veterinarians in the ranks. Under the provisions of the act of June 3, 1916, veterinarians of the National Guard in Federal service were automatically transferred into the National Army, and the Bureau of Militia Affairs reported 81 such on October 1, 1917. On checking up the papers of these men it was found that but 71 had ever been inducted into the Federal service. Three had been discharged for physical disability and four have resigned, leaving a total of 64 on active duty in various grades.

Graduate veterinarians who have enlisted and desire to take the examination for a commission are sent when practicable to one of the training camps and examined by a veterinary board while under observation. Otherwise the examinations are held at the camps.

As a rule all appointments are in the grade of second lieutenant, but appointments to the higher grades, including that of major, when the corps was in the formative stage, were necessarily given to men of unusual qualifications. Officers are promoted on their records, and on the recommendation of their superiors. So far as practicable, favorable recommendation of a general veterinary inspector is necessary in every case. During the week beginning December 10, 1917, written examinations were held simultaneously, for all veterinarians recommended for promotion, and several hundred were enlisted and promoted as rapidly as possible.

Enlisted men are obtained from voluntary enlistment, special induction ahead of their turn of men within the draft age, assignment from increments of the draft, and transfer from other organizations. By special arrangements, the inducted and some of the drafted men have been selected from certain vocations as veterinary students, agricultural students, teamsters and farmers, resulting in men of very acceptable quality and having had the advantage of familiarity with animals. The quality of men for over-seas units has been particularly good. The Veterinary Corps has been called on with other branches to make use of men physically unfit for over-seas duty, and practically all such have been placed in the auxiliary remount depots. The Veterinary Corps has also had its share of alien enemies and conscientious objectors. These things do not make for efficiency, and many complaints have been received at the quality of service rendered by men of this type, who are frequently in hospital or guard house, are absent without leave, or otherwise worthless. All enlisted men of the Veterinary Corps have been white, except about 900 constituting the personnel of Veterinary Hospitals Nos. 3, 4, and 5.

The Medical Enlisted Reserve Corps has been utilized as regards the Veterinary Corps primarily to permit veterinary students in the draft age to complete their educations. Some 260 verterinarians who graduated prior to 1918 have also been allowed to enlist in the corps. Of the latter class, 160 have been ordered to active duty July 1, at the medical officers' training camp, Camp Greenleaf, Ga., where they will be given a short training and allowed to take the examination for commission. Of the remaining 100, approximately 25 are retained in civil life at the request of the Bureau of Animal Industry and various state schools. The remaining, most of whom are married will be called as soon as the list of unmarried is exhausted.

All other members of the Enlisted Reserve Corps, i. e., graduates of the year 1918, will be ordered to duty and given two months' military training at the medical officers' training camp, Camp Greenleaf, after which all will have the opportunity to take the examination for commission as second lieutenants, Veterinary Reserve Corps. Successful applicants will be assigned to active duty as required. Those who fail will necessarily continue as enlisted men.

2. THE VETERINARY CORPS AND THE MEDICAL DEPARTMENT.

The Veterinary Corps by statute is a part of the Medical Department, and its officers and men are consequently subject to the rules and regulations governing that department. The direction of the Veterinary Corps is a function of the Surgeon General's Office, and for administrative purposes the veterinary service of the military departments is regarded as under the supervision of the department surgeon. In the entire veterinary field organization, however, there is no provision for further medical supervision. The division veterinarian is not an assistant to the division surgeon but is coequally with him a member of the commanding general's staff. Veterinarians of other units, depots, posts, etc., are likewise regarded as independent of the medical officer. At the same time they belong to the same department, and their work in sanitation and preventive medicine runs closely parallel.

This point of view has been the result of the office interpretation of Special Regulations No. 70 in its practical application and has been published in Circular Letter No. 16. This, which seems an anomalous situation, has aroused little criticism and the veterinary service appears to have fitted into its place without unnecessary friction.

3. WEEKLY TELEGRAPHIC REPORTS.

In December, 1917, was established a weekly telegraphic report from each division, auxiliary remount depot, remount depot, and embarkation depot. It covers the period ending at noon Friday and furnishes the following data: number of animals in the command, number noneffective from all causes, number of cases of communicable disease on the day of the report, and number of deaths during the week. From these figures approximate rates for noneffectives, communicable diseases, and deaths are figured for each command and for the service as a whole. The results are charted and show in a graphic way the progressive improvement in noneffective and death rates.

These reports were contemplated to show conditions amongst the green animals in the field only and do not include the more mature animals of posts or cavalry commands. They are defective in that the figures are based on the animals on hand on an arbitrary date and do not take into consideration the fluctuations of animal population during the week at individual places. They do not show admission rates. They also show relatively higher rates at the auxiliary remount depots because most of the sick of a camp are collected at the depot. They constitute, however, the only general morbidity and mortality statistics of the public animals collected thus far.

The constantly noneffective rate per thousand for all causes was 62.58; for communicable diseases was 26.84. The total deaths, including animals destroyed for glanders, was 9,001, an annual death rate per 1,000 of 68.18.

In Table 181 appears a list of the auxiliary remount depots showing the relative rates during the period. Figures for the divisions are neither shown nor of value for the reason that the serious cases are sent to the hospitals at auxiliary remount depots.

4. HOSPITAL CONSTRUCTION.

The hospital provisions at the auxiliary remount depots, as originally planned and constructed by the Quartermaster Corps, were and are crude and inadequate, and so far as known were devised without assistance or suggestion from the veterinary profession which is expected to use them in the treatment of sick and injured animals.

They consist of so-called hospital stables to which is added a small building for operating and dressing room, which possesses the added advantage of a concrete floor and a sink. No effort has been made by this office to improve these hospitals. It is considered better to start at the beginning and construct new hospitals outside the auxiliary remount depots than to attempt to add to what is now an admitted failure.

When this office protested over the further construction of veterinary hospitals without the plans first receiving the approval of the Surgeon General, the construction division of the office of the Quartermaster General suggested their construction from funds pertaining to the appropriation construction and repair of hospitals. Three such hospitals were authorized in the urgent deficiency appropriation bill for 1918—one of 1,000 animals capacity for the animal embarkation depot, Charlestown, S. C., one of 500 capacity as a base veterinary hospital at Camp Lee, and a smaller one at Camp Humphreys, Va. The plans originally prepared by Maj. Vans Agnew, in consultation with Col. Aitken and based on a British type, have been extensively revised and detailed drawings added. As now prepared they include, besides the hospital buildings, for sheltering sick animals, quarters, barracks, mess for officers and men, and also administration building, guardhouse, storehouse, etc., and require an expenditure of $475,000, which is excessive.

This hospital is designed to be an independent, self-sustaining unit and consequently must be quite complete.

Plans for an approved dipping vat have also been perfected and sent to several auxiliary remount depots for installation. One of these vats is included with each new hospital unit.

5. SANITATION.

An active campaign to improve the sanitary conditions surrounding public animals has been conducted by the Veterinary Corps since its establishment. This begins with the sanitation of the railroad and private stockyards where animals may be assembled for purchase and shipment, is continued during their transportation and their care at the auxiliary remount depots and in camp organizations. It is the duty of the Veterinary Corps to advise with regard to all conditions which may bear on the health or efficiency of animals.

Should the amendments of Special Regulations No. 70, recently admitted, be approved, a regular monthly sanitary report will be received from every command having animals. In the absence of this the office has kept informed and based its recommendations on the reports of the general veterinary inspectors, the stockyard inspectors, and to a less extent the reports of inspectors general and remount inspectors.

A multitude of minor defects have been corrected by the veterinary inspectors on the ground. The more serious difficulties are referred to this division. During the winter and spring a great deal of shipping fever incident to the assembling and transporting of many green animals developed. In the more exposed auxiliary remount depots influenza and pneumonia were common causes of death. The worst defects, in the opinion of this office, are the mud and accumulated manure and the lack of dry standings.

The mud conditions improved as the weather did, but it is felt that they will be repeated during the coming winter unless active corrective measures are adopted. The English and French have come to the conclusion that dry standings are of vital importance in keeping the animals well and it is felt we can not afford to disregard their experience.

Recommendations from this office in the direction of dry standings with or without shelter have been repeatedly made on inspectors' reports. They have met with more or less antagonism from the remount division, office of the Quartermaster General, seemingly based on the argument of the great cost involved. It may not be possible to overcome this objection, but this division is firm in the opinion that the serious conditions due to deep mud in the above-named depots are a disgrace to modern ideas of sanitation and are correctible with a reasonable expenditure. It will be both inhuman and extravagant in animal suffering and life to permit a repetition of the conditions due to mud in the past season.

6. COMMUNICABLE DISEASES.

In handling public animals it has not been possible to enforce well-known principles of animal hygiene. For this reason the morbidity and mortality rates have been high. The process of purchasing and shipping animals was very active during the entire winter and spring. Shipments were not infrequently on the road for from one to two weeks. The Federal law which requires that all animals be unloaded for feed, rest, and water once in 28 hours was not enforced. Shipments were often not unloaded from 40 to 60 hours, and even then they were placed in stock pens where accommodations were limited. A large proportion of the stock cars and stockyards were infected with influenza, strangles, etc. It was apparently impossible to clean them between the departure of one shipment and the arrival of another. Some animals were sick at the time they were loaded for shipment. Others became sick during transit, and many arrived dead or incurably sick. At destination conditions were even as bad, and sometimes worse than those to which animals were subjected in transit. The majority of the remount depots were overcrowded and were decidedly unsanitary. Many of them were located on low land with a clay subsoil and the corrals became seas of mud. As the season progressed they became worse, for the reason that the accumulation of manure and refuse from the food was added to the constantly increasing amount of mud. Estimates were made in the auxiliary remount depots for one man to care for about 15 animals. While this number may be adequate for the direct attendance on the animals it has fallen far short of covering the other miscellaneous duties amongst which the cleaning of corrals is of first importance. The force of men and the means of transportation have been inadequate practically everywhere. While 75 enlisted Veterinary Corps men were allowed to each depot, many months elapsed before the quota could be filled. The type of men for both Quartermaster Corps and Veterinary Corps has often been unsatisfactory, physical and mental defectives, foreigners, and conscientious objectors predominating. Consequently it has not been possible to keep corrals free from manure and mud or to drain them. In addition to the unsanitary standings, very few corrals were equipped with shelter in which animals could be protected against snow, rain, and wind. The principal transmissible diseases encountered have been influenza, strangles, glanders, and foot infections. Skin troubles have been rare.

Influenza, or shipping fever, was very prevalent. Nearly every animal purchased had the disease in a more or less virulent form and frequently associated with it were the usual complications like pneumonia, pleurisy, laminitis, and gastrointestinal catarrh.

Strangles has been much less prevalent. The losses from it were low except in cases in which it complicated influenza or some other diseases.

Glanders.—Among the communicable diseases of animals in an army, glanders has always been considered one of greatest importance. Since the discovery of the organism that causes it (bacillus malleus), how it is transmitted, and modern methods of diagnosis, the possibility of its control has been greatly increased.

The losses from glanders since the present war was declared have amounted to practically five-tenths of 1 per cent. The total number of horses and mules destroyed up to June 30 was 1,455. All animals have been promptly destroyed as soon as a positive diagnosis of glanders could be established.

The original source of infection was not determined in all cases. It is known that glanders existed among public animals, especially those used on the Mexican border, before war was declared against Germany. Since that time those animals and all those newly purchased have been tested for glanders before they were placed in auxiliary remount depots or in divisional organizations. Practically all public animals have been retested for glanders several times during the past year.

In the beginning of hostilities it was decided to use a combination of the ophthalmic and serological test, the last test to be used only in doubtful cases. The ophthalmic test, which has been in general use for some years by the Department of Agriculture, is applied to all animals at the time of purchase, and only those are accepted that pass this test satisfactorily. A retest is made upon their arrival at an auxiliary remount depot. Any that fail are promptly destroyed. A sample of blood is obtained from those about which there is any doubt. Those that react to the blood test are also promptly destroyed and a retest of all animals that have been in contact with the glandered animal is applied each 21 days until two ophthalmic tests are made with no positive reactions.

All animals are given this test when they are issued to divisional organizations and again when they return to the auxiliary remount depot or a veterinary hospital. When glanders appears in a divisional organization the same system of testing is adopted as that in vogue at an auxiliary remount depot. All animals that are to be shipped overseas are given this test at the port of embarkation.

The eradication and control of glanders has received solicitous and unremitting attention in this office. The military inexperience of veterinarians in the service has been a most apparent handicap, but further than this, the great majority have been unfamiliar with glanders clinically, with the application and reading of tests for its detection, and with the sanitary measures to be adopted in its control.

Correct reading of the ophthalmic test demands experience and judgment on the part of the reader and a reasonably normal conjunctiva. Animals running in corrals and those taking railroad journeys are prone to sore eyes. Consequently misinterpretations of the test are not difficult and are probably not uncommon. For these reasons and because an intradermic test is in use overseas, the development of an intradermic technique has been started.

7. SUPPLIES.

All veterinary supplies are purchased and issued by the supply division of the Surgeon General's Office. Maj. D. S. White, Veterinary Corps, National Army, became associated with this work on October 29, 1917, and has since been closely identified with it.

The supplies on hand, when the Veterinary Corps passed under control of the Medical Department, were those transferred from the Quartermaster Corps. They were valued at $200,000 and were largely of a type little useful in the present emergency. In fact, a canvass of the veterinary supply and equipment situation revealed the absolute necessity for a complete new list of articles, both expendable and nonexpendable.

To correct this defect the supply division on September 29, 1917, issued "Tentative Veterinary Tables," constituting Article XXII, paragraphs 966 and 977 of the Manual Medical Department. These were not adequate. The items listed were of the wrong type, bulky, heavy, often put up in fragile containers, and in no sense adaptable to modern war conditions. New supply and equipment tables were therefore compiled which were formally approved by the General Staff January 22, 1918. They include tables of medicines, disinfectants, and antiseptics, list of instruments, stationery, and miscellaneous supplies, contents of veterinary chests and wallets, equipment of the veterinary field unit, the divisional mobile veterinary section, and of the veterinary hospital units. There are now being printed and will appear as amendments to the Manual Medical Department, paragraphs 902, 966, 967, and 978 to 992, respectively, taking the place of Tentative Veterinary Tables. Mimeograph copies of them have been distributed throughout the services of the interior for the information and guidance of those concerned; copies have been sent to France.

About November 15, 1917, realizing the necessity for a radical change in veterinary supplies for field and hospital use, the British War Office was requested to loan the Surgeon General of the Army a complete set of veterinary field chests and wallets for inspection, and to serve as models to be patterned after if deemed suitable. They were received and after careful examination were finally adopted as models for our Army.

The two fundamental reasons why the British equipment was selected were:

(*a*) The plan of organization of the Veterinary Corps is modeled closely after British Army Veterinary Corps. Under it sick and inefficient animals are treated, except for first aid and in emergencies only, in line of communication veterinary hospitals. The supply system fits in with this plan.

(*b*) The British Veterinary Corps had spent many years evolving a suitable supply system, keeping constantly in view economy in weight and bulk and simplicity in distribution. During the three or more years on the western front in the most strenuous warfare the world has ever known, ample opportunity was afforded to test in a most practical way the efficiency of this equipment.

8. ORGANIZATION OF THE VETERINARY SERVICE.

General inspectors.—The territory of the United States was divided into five zones and five experienced officers assigned thereto as general veterinary inspectors about December 15, 1918.

War Department orders direct that these officers shall act as general veterinary inspectors in their territory, cooperating with the Bureau of Animal Industry therein, in the disinfection and sanitation of public stables, yards, and stock cars used in the collection and transportation of horses and mules intended for or in the military service, inspecting and reporting upon the sanitary condition of yards, depots, veterinary hospitals, horse lines, stables, etc., belonging to or used by the War Department and not under the control of the department commanders; the methods used in handling animals therein, the efficiency of veterinary officers and upon such other subjects as have a direct bearing on the improvement of the veterinary service or on the prevention of disease and inefficiency among public animals. They are authorized to make recommendations to local commanding officers of the remount division, Office of Quartermaster General, for the correction of conditions prejudicial to the health and efficiency of public animals and are directed to render their reports direct to the Surgeon General of the Army.

By virtue of the broad powers of these orders they act as both inspectors and instructors and are encouraged to remain at a station not only long enough to inspect it but also to correct defects so far as possible and to improve the efficiency of veterinary personnel by instruction and advice. Wherever a serious outbreak of communicable diseases, like glanders, has occurred, the inspector is instructed to assume veterinary charge of the situation until the epidemic has been brought under control.

In general the activities of these inspectors have been of the utmost importance in advancing the efficiency of the veterinary service. Their work in connection with the inspection of stockyards can not fail to have its beneficial effect on the live-stock industry of the entire country.

Veterinary officers, as stockyard inspectors to the number of 10, operating under orders from this office, were assigned to important shipping points for a time but have been gradually replaced by lay inspectors of the Bureau of Animal Industry who report entirely to the senior purchasing officers of the zones.

Relatively high mortality in several shipments of animals resulted in very thorough investigation by this office. Two hundred and seventy-seven animals died in a shipment from Camp Grant to Newport News, mostly at Covington, Ky. Five died at Newport News, 26 at Camp Meade, and 11 at Fort Ethan Allen, all in shipments from Camp Upton. Suspicions of poisoning were aroused and given considerable publicity in the press. It was impossible to definitely fix the cause of death since the lesions as a rule were those of a simple gastrointestinal catarrh, but the conclusion was forced that exposure to long periods without rest, food, or water while under the strain of a railroad journey was the leading if not the only causative factor. The so-called 28-hour law had gone by default because the War Department had ruled in 1916 that in emergency it was nonapplicatory to shipments of public animals, and officers accompanying were authorized to sign releases which in active practice meant extending the time in every shipment without unloading almost indefinitely. In the Fort Etahn Allen shipment, 20 mules traveled 62 hours without food, rest, or water, and 11 died. This state of affairs resulted in a War Department ruling concurring with recommendation of this office that the 28-hour law should be hereafter enforced except in extraordinary emergency.

Ports of embarkation.—A veterinary service is authorized at ports of embarkation and has been organized at Newport News, Va. The senior veterinary officer is designated as the post veterinarian and has supervision of the veterinary service of the port and of animal transports. A veterinarian is assigned to each animal transport, permanently, so far as practicable.

Divisions.—The veterinary personnel of an Infantry division at full strength consists of 12 officers and 51 men.

Service of camps.—As rapidly as the divisions have been moved from indivisional cantonments, a camp veterinary service has been organized by the assignment of a camp veterinarian, a meat and dairy inspector, who is assistant to the camp veterinarian, and five enlisted men, two of whom are experienced in meat-inspection work. When the number of animals requires, an additional veterinary officer and three additional enlisted men are provided. The camp veterinarian is on the staff of the camp commander and is his adviser in all veterinary matters. The duties of the camp veterinarian as regards units and other organizations in the camp are similar to the relations existing between the division veterinarians and the units of the division. He is likewise responsible for an efficient meat and dairy inspection. The camp veterinarians have been selected men contemplated to be in training for the position of division veterinarian in these camps when divisions are to be formed later.

Military posts.—A veterinary service is maintained at only a few military posts. As a rule this assignment consists of one officer and three men since the demands on such service are limited. The animals kept at posts are as a rule old and seasoned and few places have capacity for any large number. This does not refer to large reservations on which detached cavalry regiments are stationed, for in such cases the veterinary service is assigned to the organization rather than to the place. When an experienced officer is available as post veterinarian, however, and other commands are present it is contemplated he shall act in a capacity similar to that of the camp veterinarian and coordinate the veterinary service.

Veterinary service in the theater of operations.—Besides the field unit attached to mobile commands and the divisional mobile veterinary section, both already described, the following veterinary hospital organizations are provided:

(*a*) The Corps Mobile Veterinary Hospital.
(*b*) The Army Mobile Veterinary Hospital.
(*c*) The Base Veterinary Hospital.
(*d*) The Veterinary Hospital (L. of C.).

(*a*) The Corps Mobile Veterinary Hospital (T. of O. No. 109) is provided at the rate of one to each corps. Personnel, 2 officers and 35 enlisted.

The equipment is similar to that of the mobile section since their duties are similar, both being evacuating units. The mobile hospital does not have the pack mule of the divisional unit but has a 2-mule ambulance.

(*b*) Army Mobile Veterinary Hospital (T. of O. No. 330). One supplied for each field army. Personnel, 4 officers and 144 enlisted.

While much less mobile than the corps unit, this hospital may serve as an evacuating unit or as a stationary hospital, depending on circumstances. Its hospital equipment is practically one-half that of a veterinary hospital and it is designed for 500 patients.

(*c*) Base Veterinary Hospital. The personnel and equipment are identical with those of the Army Mobile Veterinary Hospital.

(*d*) The Veterinary Hospital (T. of O. No. 33[illegible]) is supplied at the rate of 5 to each corps. Personnel, 8 officers and 311 enlisted. One captain or first lieutenant, 1 sergeant, first class, 1 sergeant, and 9 privates, first class, or privates are sanitary troops.

This is the typical fixed hospital of the line of communications with a standard capacity of 1,000 patients. They are generally operated in groups and designated as the receiving hospitals, mange or contagious diseases hospitals, and general hospital of each group.

9. TRAINING CAMPS.

It became evident very early in the history of the Veterinary Corps that its efficiency was seriously imperiled through lack of military experience on the part of veterinary officers. There was practically no leaven of trained men to help the untrained and it was too much to expect men fresh from civil life to readily adapt themselves to service conditions. The problem of organizing and training field units for overseas was also urgent with scarcely a competent instructor available.

(*a*) *Camp Greenleaf.*—The veterinary section of the medical officers' training camp, Camp Greenleaf, opened in February, 1918, with a class of 50 officers. The first class graduated April 20th, the next of men on June 20, and arrangements are now complete for a graduating class of 100 each month, each class to have two months' training. The first month has 180.5 hours of instruction devoted to purely military subjects. The medical officers of the training cadre of the camp are utilized as instructors in most of the military work to the advantage of the Veterinary Corps. The second month continues the military but includes 64 hours of general veterinary training. The veterinary officers are organized as separate companies, and their work and progress have been reported as excellent. Every effort is made to send all men from civil life to the camp for their first active duty. The enlisted veterinary detachment is made up of 40 men semi-permanently on duty, members of the Medical Enlisted Reserve Corps who are graduates preparing for examinations for commission, and a few men inducted into the service and coming from points east of the Mississippi.

(*b*) *Medical officers' training camp, Fort Riley, Kans.*—The veterinary section of the medical officers' training camp at Fort Riley, Kans., was established on February 4, 1918. It is used entirely for the training of enlisted men, chiefly those inducted into the service from the States west of the Mississippi. Besides training in the military and special duties of the veterinary soldier, classes are maintained at the schools for cooks and bakers and horseshoers, and men given these courses are assigned to overseas units as fast as ready.

(*c*) *Veterinary training school, Camp Lee, Va.*—It also became apparent quite early that the facilities at Camp Greenleaf would prove inadequate for the training of the officers and men and for the organization of overseas units, and the establishment of a purely veterinary training school was recommended in January of this year. This school was authorized on March 22, 1918. It consisted of barrack accommodations for 1,600 men and quarters for 95 officers, with an administration building, lecture hall, and infirmary.

The site selected was a desirable one in the midst of Camp Lee. The construction was started promptly, and the commandant, Lieut Col. E. A. Sturges, National Army, and the senior veterinary instructors were early on the ground. Much delay was experienced in securing men from the draft and it was early in June before any considerable number was on hand.

10. LABORATORY SERVICE.

A veterinary laboratory was established by War Department orders on January 19, 1918, at Philadelphia, Pa., Maj. S. H. Gilliland, Veterinary Corps, in charge. Laboratory rooms are loaned by the University of Pennsylvania and equipment and supplies furnished by the Medical Department. The purpose of the laboratory is to study the cause, prevention, and treatment of influenza, strangles, and pneumonia amongst public animals; to examine and determine the therapeutic value of sera and other remedial agents; to prepare mallein and other laboratory products; and to make general bacteriological and pathological examinations. This laboratory has manufactured a large amount of mallein and turned it over to the Bureau of Animal Industry. The bureau is at present supplying all mallein used by the Army. The volume of complement fixation tests for glanders became greater than could be handled by this laboratory with the assistance of the laboratory of the Bureau of Animal Industry, and arrangements were made to place a veterinary officer trained in laboratory work in the department laboratories at the Letterman General Hospital, San Francisco, Cal., Fort Sam Houston, Tex., Atlanta, Ga., and Fort Leavenworth, Kans. These officers were all instructed at the Philadelphia laboratory in uniform technique. Veterinarians in the field are authorized to call on the base-hospital laboratories for simple laboratory examinations, but all more extensive work, including blood tests and pathological work, is required to be done at one of the aforementioned department laboratories. The results from this arrangement have been most satisfactory.

11. MEAT AND DAIRY INSPECTION SERVICE.

The responsibility of the Veterinary Corps in the matter of meat inspection was recognized in the national defense act. Special Regulations No. 70 directs that the Veterinary Corps provide for the inspection of meat-producing animals before and after slaughter and of dressed carcasses, and for the inspection of dairy herds supplying milk to the Army, provides for a meat inspector attached to headquarters of each division, and outlines his duties.

The history of meat inspection for the military forces of the United States, so far as its relation to the veterinary profession is concerned, began at a much earlier date with the appointment on July 8, 1901, of Dr. Charles W. Johnson, meat inspector, subsistence department at large, United States Army, by transfer from the Bureau of Animal industry.

This appointment was predicted in Circular No. 3, Office of the Commissary General, issued June 7, 1901. This circular provided that meat purchased by the subsistence department would be subject to "inspection in addition to that exacted by the Secretary of Agriculture." This inspection contemplated a supervision of the selecting, curing, smoking, canning, and packing of all meat food products purchased for the military forces.

Taken in the larger sense, the Army meat inspection was a direct outgrowth of the embalmed-beef controversy which followed the close of the Spanish-American War. Inquiry into the charges that certain articles of food furnished the military forces at that time were unfit for issue, brought out repeatedly questions concerning the methods used in the preparation of meat food products—the quality of the beef purchased and method which entered into the manufacture of meat food products and whether there was a representative of the Army present during its preparation.

Following this inquiry, inspectors from the board of trade were employed for inspection duty by the subsistence department. These inspectors were paid upon a basis of the number of boxes or barrels inspected, and meat was purchased very largely under the general rules governing board of trade products. That this method of inspection was not satisfactory is evidenced by some of the complaints concerning the work. The inspectors were disinterested, doing Army work only incidentally, and were not always available when needed.

In 1914 the comissariat of the Panama Canal Zone requested that the inspection of Army meats be extended to include the inspection of meat for the Panama Railroad Co. at the request of the general purchasing officer of the Panama Canal Zone. With the increase of the military forces in 1916, the inspection of the Army was increased by the employment of veterinarians by the depot quartermaster. These men were later taken into the Veterinary Reserve Corps and the work of meat inspection extended to the camps. A school for veterinary officers was established at Chicago depot for the purpose of giving instruction in meat inspection, and in 1917 a similar school for enlisted men was established at that place. New delivery points were opened from time to time as the purchase of meat supplies increased until there are at this time 26, with inspectors stationed at 23 cities, completing the inspection of approximately 10,000,000 pounds per week. There are on duty at the Chicago office 46 officers and 34 enlisted men, with 13 officers under instruction.

The inspection of all meats and meat products purchased for the Army through the Chicago depot has been efficiently conducted by the Veterinary Corps. The meat and dairy service in the camps has been less satisfactory. This camp service included inspection at the local commissary on receipt, while in storage and at issue, inspection of local slaughtering places and their methods of handling, storing, processing, etc., and inspection of milk herds and dairies, and is of great importance.

TABLE No. 181.—*Annual rates per 1,000 horses and mules.*

Camps.	Constantly non-effective, all causes.	Communicable diseases.	Deaths.
1. Lee	287.51	189.89	248.07
2. Sevier	194.08	93.87	212.49
3. Grant	189.52	50.02	153.12
4. Sherman	188.69	123.85	217.76
5. A. E. D., Newport News	155.44	26.45	75.73
6. Sheridan	139.52	68.85	133.85
7. Lewis	135.65	35.79	158.87
8. Shelby	132.88	53.44	123.25
9. Fremont	132.33	95.09	116.14
10. Greene	130.52	92.63	167.45
11. Hancock	123.56	70.09	71.03
12. Beauregard	122.80	50.73	96.13
13. Dix	119.32	79.54	319.93
14. Devens	103.25	61.40	103.25
15. El Reno	94.39	52.68	63.79
16. Logan	92.58	54.70	76.67
17. Upton	90.35	47.78	162.94
18. Bowie	88.25	70.33	58.53
19. McClellan	83.51	28.93	77.17
20. Gordon	75.46	22.65	47.39
21. Dodge	73.56	14.17	42.59
22. Taylor	71.28	38.91	101.60
23. Funston	68.87	44.29	83.21
24. Custer	64.55	31.62	51.58
25. Doniphan	60.23	6.34	56.07
26. Pike	60.14	19.58	63.23
27. Jackson	59.55	22.65	48.77
28. Johnston	58.84	8.47	20.91
29. Wadsworth	55.22	23.23	90.35
30. Cody	54.32	16.81	54.96
31. Travis	54.01	15.76	62.45
32. Meade	53.99	25.46	114.13
33. Wheeler	51.08	14.45	159.67
34. Front Royal	51.04	18.74	17.93
35. MacArthur	37.15	18.29	52.02
36. Kearney	27.92	17.49	106.11
37. Keogh	22.80	4.72	54.28

XIX. DIVISION OF ARMY NURSE CORPS.

During the past year the Army Nurse Corps has increased enormously. The day war was declared there were but 403 nurses in the service—233 Army and 170 reserve. On June 30, 1918, there were, exclusive of those on final leave awaiting discharge, 2,000 members of the Regular Corps, and 10,186 reserve nurses, making a total of 12,186. These nurses are stationed at 198 stations in this country and abroad. The number serving overseas is 5,350, including those already abroad and those awaiting transportation in New York. These stations include all the cantonment hospitals, general hospitals, base hospitals, aviation stations, and many Coast Artillery posts, as well as miscellaneous stations. Fifty nurses have been requested for duty at Las Casas, San Juan, P. R., and have been mobilized for that station, and a group of 8 anesthetists has been mobilized for over-seas service. Also in response to a cablegram from the commanding general, American Expeditionary Force, a group of 555 nurses was ordered to the mobilization station for service abroad. These nurses were selected from among those on duty in the cantonments, and were sent to the mobilization station in New York City in the course of a very short time.

The nurses of Base Hospitals Nos. 1 to 50, organized under the American Red Cross, were all assigned to temporary duty in the cantonments pending over-seas orders, and, with the exception of 5, have been ordered abroad or are awaiting transportation at the mobilization station in New York. The last 5 will be ordered to the mobilization station in the course of a very short time. Base hospitals after No. 50 will be organized by the Army, and the nurse personnel will be selected from nurses who have been on duty in the army hospitals in this country, thereby enabling this department to select those who have demonstrated their professional and physical fitness for the service. Special hospitals, No. 114 for orthopedic cases and No. 115 for head surgery, No. 116 for fracture, and No. 117 for psychiatric cases, have also been ordered abroad, though No. 115 is still at the mobilization station in New York awaiting transportation. Five thousand three hundred and fifty nurses serving abroad are distributed as follows:

British forces	755
French forces	14
American forces	3, 323
Awaiting transportation or en route, mobilization station	1, 258
Total	5, 350

This number includes nurses sent to the American Red Cross Military Hospitals Nos. 1, 2, and 3 and the American Ambulance, which were organized by the American Red Cross, but brought under military control shortly after the United States entered the war.

During the past year an outdoor uniform has been adopted for members of the Army Nurse Corps. As it was impossible to obtain forest-green or olive drab woolen material, it was found necessary to select navy blue. This has been very satisfactory and has been reported to be the best-looking nurses' uniform in Europe. Recently members of the Army Nurse Corps have been authorized to wear the war-service chevron on the left sleeve under the same conditions as it is allowed for officers and enlisted men. The uniform adopted has been placed in the uniform regulation book and removed from the Manual for the Medical Department.

Shortly after the declaration of war a clothing allowance for nurses was requested, but was disapproved by the War Department, as all clothing allowances had at that time been discontinued. As, however, quite an expensive equipment was needed by the nurses going overseas, the Red Cross agreed to furnish it to all nurses going abroad at a cost of approximately $200 each. As it is considered advisable for Army nurses serving in the United States to wear the outdoor uniform at all times, all nurses will be required to purchase these garments as soon as the bill for the increase of pay goes into effect. Exceptional equipment will still be issued by the Red Cross to nurses ordered overseas.

There were some complaints during the months of November and December, 1917, of shortage of nurses in some of the cantonment hospitals, great numbers of acutely ill patients having been admitted suffering from contagious diseases, etc. The delay in sending a sufficient number of nurses was due in part to the fact that quarters for their accommodation were not available. They were sent, however, as rapidly as possible, so that in a short time the need was fully met. Steps were taken to build additional quarters, other buildings, tents, and so forth, being used in the meantime for the nurses. They were, however, very much crowded and conditions were not at all satisfactory during this period. Quite a large sick report resulted at some of the posts, Camps Lee and Shelby in particular. Infirmaries for the care of nurses on sick report have since been constructed at all the cantonments and at several of the general hospitals and have been quite satisfactory.

The mess allowance of nurses has been increased from 40 to 60 cents at places where there are sales commissaries and to 75 cents where there are none. The subsistence allowance of nurses on detached duty in this country has been increased from $1 to $1.25 per day and to $2 for those on detached duty in Europe.

During the year 11,299 application blanks and circulars of information have been sent out and 3,196 returned.

A bill for the reorganization of the corps was sent to Congress last autumn, which provided for an increase of the base pay of nurses from $50 to $65; for retirement at the expiration of 20 years' service; for the creation of positions of assistant superintendents, and for directors and assistant directors of nursing service abroad. This bill became a law on July 9, but unfortunately the base pay of the nurses was increased to $60 only, and the chief nurses' pay, through accident, decreased to $10 over their pay as nurse, instead of $30 per month as was authorized in 1910. This, it is hoped, will be corrected immediately. The clause providing for retirement after 20 years' service on three-fourths pay was eliminated entirely, but it is hoped the objection to this may be overcome and some provision made later for retirement. There has been considerable agitation among the nurses of the country for rank. At this time no action has been taken so far as is known, either by regulation or legislation.

Army nurses have been assigned to duty at the war emergency dispensary which was established to look after the physical welfare of the large number of clerks who have come to Washington for service in the various departments of the Government. These nurses number at the present time 32, and are assigned to duty at various rest rooms of the large office buildings, as well as to visiting work in connection with those who need attention at their homes.

With regard to a corps of women to augment the nursing service in case of need, it has been decided to organize a school of nursing with headquarters in Washington, a three-year course to be given at the various large Army hospitals in this country, with an affiliation of one year at the civil hospitals in those branches of nursing in which training can not be adequately given in the Army hospitals. This has necessitated considerable rearrangement in the assignment of chief nurses, many of the chief nurses, though excellent executives, not having had experience in training school management.

It has also been decided to assign small groups of colored nurses at some of the hospitals in this country as soon as satisfactory quarters for their accommodation can be provided. The same plan has been decided upon in connection with a group of Cuban nurses, who have offered their services to the War Department.

Early in the year a change of regulation placed the full responsibility of ward management upon the head nurse, which responsibility has hitherto been shared by the wardmaster.

Ellis Island, the place at which the nurses were formerly mobilized to await transportation, having been taken over as an Army hospital, a new mobilization station was selected, and established at the Knott chain of hotels, in New York City, with headquarters at the Holley Hotel. This new arrangement has been quite satisfactory though some complaints have been made in regard to conditions at two of the hotels used. Nurses will not be sent to these two after the present number has departed.

Sixty-five nurses attached to Base Hospital No. 8 of the Post Graduate Hospital, New York City, sailed for Europe in July, 1917, on the S. S. *Saratoga*, which was rammed in New York Harbor by the incoming S. S. *Panama*. This necessitated the immediate evacuation of the ship. The nurses were taken aboard all sorts of small craft in the bay and returned to Ellis Island the next day, many of them in a state bordering on shock. With but few exceptions and because of having to leave the ship with no time to collect their belongings, they lost practically everything they owned. The war council of the American Red Cross, however, immediately appropriated a sum to reequip the entire group and gave $30 in gold to each nurse, there being no law at that time for the Government to reimburse them for the losses they sustained. "The act to provide for the settlement of the claims of officers and enlisted men of the Army, for loss of private property destroyed in the military service of the United States" has since been amended by act of July 9, 1918, (H. R. 12281) and members of the Army Nurse Corps who lose private property in the military service, will have it replaced or its value recouped.

In view of the high cost of clothing and equipment, particularly overseas, it has been recommended that the Quartermaster Department carry the necessary uniform and equipment for sale to members of the Army Nurse Corps at cost. No decision has yet been received in regard to the matter.

By act of Congress approved October 6, 1917, provision was made for compensation of nurses disabled or injured in line of duty, and for insurance against permanent disability or death.

A supervising nurse for the nurses on duty in France having been requested by Gen. Pershing in October, 1917, Miss Bessie S. Bell, who had an excellent record for a number of years as chief nurse, Army Nurse Corps, was sent to assume the duties of that position. Miss Grace E. Leonard, chief nurse, Army Nurse Corps, was assigned to a similar position in England.

During the year 1,843 nurses have been appointed in the Army Nurse Corps, 25 orders revoked before oath, and 1,780 oaths taken. Nine thousand six hundred and thirty reserve nurses have been assigned to active duty, 167 orders revoked and 9,415 oaths taken. One hundred and forty-seven nurses were discharged from the Army Nurse Corps, and 4 deaths; 550 reserve nurses were relieved from active service, and 18 deaths.

Owing to the number of deaths, it is believed it would be very desirable if a plot at Arlington could be set aside for nurses who die in the service.

For the first time in the Army, graduate dietitians have been employed in the Army Hospitals of this country and abroad and have been most satisfactory. The work has come under the jurisdiction of the Army Nurse Corps office and 164 have been employed.

XX. Library of the Surgeon General's Office.

During the fiscal year 1917–18, 547 books and 5,890 pamphlets were presented to the library and 141 portraits of physicians were added to the collection. The library now contains 196,243 bound volumes, 34,316 unbound volumes, and 352,523 pamphlets, in all, a total of 583,082 books and pamphlets, with 5,390 portraits of physicians. This collection makes the library of the Surgeon General's Office second only to the library of the Paris Medical Faculty in size and number of volumes; in other words, it is now the second largest medical library in the world. Exclusive of transactions of societies the number of current medical periodicals now received in the library is 1,293. This is exclusive of 148 separate German periodicals which have not been received since 1915. The total collection of medical periodicals is the largest and most useful in existence. During the year, 2,500 volumes have been sent to the bindery, but the number of current periodicals which stand sadly in need of binding is still very large.

In the fall of 1916, the twenty-first and last volume of the second series of the Index Catalogue was printed, making a total of 37 volumes in the first and second series. The two series comprised entries of 346,176 author titles, under which 171,911 volumes and 317,795 pamphlets were listed; and 1,420,631 subject titles, including 304,962 books and pamphlets and 1,156,669 journal articles. The number of portraits of physicians catalogued in the first and second series was 5,249. During 1917–18, the first volume of the third series of the Index Catalogue has been in preparation, the work of redaction and printing having been to some extent impeded by the exigencies of war-time service in this office and elsewhere. This volume, containing the accumulated literature (authors and subjects) from "A" to "Armies" is now completely in type, and will be published in the autumn of 1918. In starting the third series of this publication, which is now regarded as indispensable to scientific physicians and medical libraries everywhere, it is worth while to cite a few of the opinions expressed as to its value by the medical profession. It is regarded as the only work of the kind which can be placed in comparison with the great medical bibliographies of Haller and Callisen, which it easily surpasses in scope and extent, covering, as it does, the major part of the medical literature of the world, from the earliest times. In respect of practical utility, it may be said that it contains practically every item of any real value to medical science. At the Billings memorial meeting held at the Johns Hopkins Hospital in May, 1913, Dr. (now Col.) William H. Welch expressed the opinion that the Index Catalogue is the most important contribution yet made to American medicine (as distinguished from laboratory and clinical contributions of Americans to medical science) in the nineteenth century. In a printed communication of 1914, Col. J. George Adami, Royal Army Medical Corps, has said of the Index Catalogue and Index Medicus: "It is difficult to realize of what service to science these two publications have been to medicine the world over; or what has been the influence also to medicine the world over, of the existence of the marvelously progressive library of the Surgeon General's Office, and its service in bibliographical research."

In paragraphs 132–133 of the Manual for the Medical Department of the United States Army (1916), the value of this library as a place for research and of its Index Catalogue as a tool is brought to the attention of medical officers. The true functions of this library, first as an adjunct to the administrative mechanism of our Army Medical Department, second as a national collection of medical books, were already stated as far back as 1878, in an address by Dr. Oliver Wendell Holmes, in which the following brief was filed for Dr. Billings's project of printing an index catalogue of medical literature: "When we have a noble library like that at Washington, and a librarian of exceptional qualifications like the gentleman who now holds that office, I believe that a liberal appropriation by Congress to carry out a conscientious work for the advancement of sound knowledge and the bettering of human conditions, like that which Dr. Billings has so well begun, would redound greatly to the honor of the nation. It ought to be willing to be at some charge to make its treasures useful to its citizens, and, for its own sake, especially to that class which has charge of health, public and private."

In the last year the Medical Corps of the Army has had charge of the health of a large part of our male population, with the prospect of even greater responsibilities and of the enrollment of most of the physicians of the country in this service as the war wears on. The liberal appropriations made by Congress for the library have been doubled for the coming fiscal year. This places the library in position to meet its obligations in connection with the large amount of foreign medical literature which has accumulated in Europe during the war and which could not be transported overseas while the war goes on. For some years past it has been impossible to bring a good deal of useful and valuable material in this library to the front, from sheer lack of space. This difficulty may now be obviated through the fact that the large room in the southwest wing of the Army Medical Museum, directly underneath the library hall, has been vacated by the Adjutant General. It is proposed that this room be utilized as a combined public reading room and repository for the collections of bound and current periodicals (south end) and of public documents (north end). This will give better administration, since the literature most called for by the visiting medical public, entering on the same floor, is usually periodical literature. The removal of the bound periodicals and public documents from the bookstacks in the present library hall (second floor) will afford space for a much-needed rearrangement and reclassification of the remaining books in these stacks, with abundant shelf room for new accessions for many years to come. In order to accomplish all this it will be necessary to lay a cement flooring in place of the worn-out plank floor in the large room on the first floor, to set up adequate iron bookstacks in this room (for insurance against fire), and, for economy of administration and messenger service, to excavate and construct an iron staircase leading directly from the upper to the lower library hall. It is urgently recommended that support be given to this project and that it be carried out as soon as practicable.

During the past year, the large and valuable collection of public documents has been completely overhauled, rearranged, and reclassified. The collections of portraits and autographs of medical celebrities are in process of mounting in special portfolios. The unique collection of fifteenth-century books (medical incunabula) now numbering 240 separate items, has been carefully segregated from all parts of the bookstacks, and is thus accessible to students of medical history. A catalogue of this collection by the librarian has just been printed (Annals of Medical History, N. Y., 1917–18, I, 301–315).

XXI. The Medical Museum.

During the past year the museum has taken on a new life, there being a deliberate endeavor on the part of the Surgeon General to make preparation for the study of the medical material of this war upon a modern, scientific basis, to provide facilities which only the National Government may provide, and to place them at the disposal of the scientific men of the present day to the end that medicine may be advanced by the study of large groups, where community service studies may be developed and men really and truly assist and guide each other toward the attaining of the truth.

To this end officers are on duty in the pathological laboratory supervising the collection and preparation of the pathological material. Maj. Shufeldt is arranging the collections and cataloguing them as they come in, with proper cross-references, to the case histories and post-mortem protocols of each individual specimen.

There is a deliberate endeavor upon the part of the officers in charge and those engaged in the pathological work to make the pathological findings immediately available to the clinician and at the same time to file the material away in such shape that it may be available for research work at a later date by large groups of men, where a large group may work together over exactly the same material so that their findings will be group findings, where individuals may be helped and the studies advanced by the work of the group as a whole, and where the finished work may be filed away for future study, so that the individual material itself may be available again should it be found necessary to make the studies over in the light of a later and better technique.

There has been established an instruction laboratory for the production of moving pictures, animated diagrammatic drawings, still photography, lantern slides, photostat copies, black and white and color drawings, etc., to the end that medicomilitary matters in this way may be properly illustrated.

An interesting series of these films are the "animated diagrams" showing operative procedure, battle procedures, etc. These films will be used in teaching in the various medical schools developed by the Surgeon General's office, and they will be available for the medical schools in teaching medicomilitary medicine when the war shall have passed, and also serve as historical data.

Among these films are two of special interest. One of these shows the pathway of the nerve impulses in nystagmus, and why it is that the one movement is slow and the other rapid. The diagram shows the impulses starting in the semicircular canal, then going up the eighth nerve to the reflex centers in the medulla oblongata, then out through the motor nerves to the muscles moving the eyeballs, thus producing the slow deviation of the eyes in nystagmus. Next follows the correction of the deviation through cortical control, the passage of the nerve impulse downward from the cerebral cortex to the nerves of the antagonistic muscles of the eyeballs producing the quick return of the eyes, thus completing the nystagmus cycle.

In the femoral hernia operation, the artist's hand first appears drawing in the torso of the woman; then the bony pelvis appears, then Poupart's ligament, then Gimbernat's ligament, and when these ligaments are in place, then the aorta subdivides, the internal and external iliacs drop into place and the femoral artery goes through under Poupart's ligament to its own place. Then immediately follows the vein, following each one of the arteries; then the obturator artery, both in its ordinary and its extraordinary position, appears. Then the intestines appear in peristalsis, and the loop of the ilium attaches itself and enters through the crural canal and the femoral hernia is formed. Then the transparency fades away, leaving on the screen the original hernia, with the intestine within it. Then the knife falls into place, makes the proper incision, the retractors come in and open the tissues up, and layer by layer the operation proceeds with the moving diagram ever changing and making a perfectly clear outline of every detail of the operative procedure.

It is proposed at the first opportunity to obtain a picture of the femoral hernia operation itself being performed, and then place the two in juxtaposition for the purpose of teaching the young medical men.

Films are being exhibited over a circuit comprising about 450 camps, cantonments, colleges, etc., more than 300,000 feet of film having been shown during the week of writing this report, and the demand is steadily increasing.

The laboratory has coordinated very largely with all of the other bureaus of the War Department, having done much work for the photographic division of the Signal Corps, the Ordnance Department, the Engineer Corps, Commission on Training Camp Activities, Gas Defense, Council of National Defense, Gas Mask Division, General Staff of the Army, Adjutant General's Office, Committee on Public Information, Liberty Loan Division, American Red Cross, and others.

First-class artistic work is also being done by men who have been thoroughly trained in this work in civil life before they entered the service. One of the rules of the anatomical art department of the instruction laboratory is that no man will be accepted as an artist in this group unless he has supported himself for at least four years in civil life by his art alone.

There are two high-class wax modelers connected with the museum, one of whom has been detailed abroad; the other is here, producing work of a high grade.

It is also intended, at a later date, to use high-class sculptors for the work of facial reconstruction of men who have suffered injury to the head and face.

The endeavor of the instruction laboratory has been throughout, that if the work desired was United States work then it should be done with the proviso that the bureau for which it was done would replace the material so used to the Surgeon's General's office, so that the actual effect was that the officer desiring the material simply furnished the raw material and the negatives owned by the Surgeon General's office were used to furnish the copy, thus saving the United States a large amount of money.

Nearly two years since drawings were made by Mr. Fitz Simons, an architect of Washington, for the erection of a new building, looking to the better storage and care of the valuable material gathered here, together with study rooms, and assembly rooms where the medical professions might get together for the benefit of their patients and of the nation, and where their work might be concentrated and they could utilize the literature collected for this purpose by the United States. These plans and thoughts were formulated and transmitted to the Commission of Fine Arts of the District of Columbia, to whom has been assigned the task of beautifying this great city of Washington and the arranging of its educational institutions. The thought appealed to them in such a way that they promptly accepted the idea and assigned a building site in their annual report to the Congress of the United States, in the square bounded by Four and one-half, B, Sixth, and A Streets, SW. The original plans were afterwards modified, so as to make the exterior of the building correspond, with the designs of the National Commission of Fine Arts, so that the building when erected would correspond in every particular with the plans of the commission for the beautification of the city of Washington.

XXII. Medical and Surgical History.

Special Order A. G. No. 196 (Aug. 23, 1917) created a "board to collect and prepare materials for a medical and surgical history of America's participation in the European War." This board at the outset ascertained by correspondence the status of similar projects in England and France. Its own existence was made known to the Medical Corps by means of a circular, wherein medical officers in the field were urged to keep notebooks of their own concerning important matters of personal observation; if responsible for medical and surgical records at the front or at a hospital, to see that such reports are as complete and accurate as possible, and to take every precaution against loss of records, whether in the possession of the medical officer, or in the attempt to transmit such records. Physicians and surgeons were encouraged to make as liberal notes as the circumstances permit concerning important cases, and to lodge such memoranda with the historical board; being assured that the maker of such notes would not impoverish himself in the transfer of such materials. It was made clear that the making of this history would not be a bureaucratic undertaking, but democratic, giving credit wherever credit was due.

In a subsequent printed circular of the Surgeon General, medical officers were urged to keep this historical purpose in mind throughout the war; to contribute official and private writings (their own or others) having historical interest or value; to collect printed matter, pictures, specimens, models, and other significant objects, and materials secured by exchange or otherwise from representatives of other governments. The board is made responsible for the receipt, custody, cataloguing, and acknowledgment of all materials received.

Commanding officers of base hospitals have been authorized to make subject indices of medical and surgical cases, and to make and transmit histories of epidemics, or of unusual cases. Histories of cantonments are especially desired and may have been sent in. Arrangements have been made for safe custody and transportation of historical materials accumulating on the western front and in Italy.

Through the courtesy of The Adjutant General's office and the Provost Marshal General's office the medical records of recruitment and mobilization will be at the command of the Surgeon General's office for the purpose of history.

Arrangements have been made whereby The Adjutant General's office allows the records of physical examinations to be taken to the medical record division of the Surgeon General's office where the statistical material is taken off. These records are then returned promptly to The Adjutant General's office for filing.

Arrangements have also been made by the medical record division with the Provost Marshal General's office whereby a copy of the physical examination for each man placed in class 5, by local boards as permanently disqualified for military service is sent by the local boards through the adjutant general of the state to the Surgeon General's office for filing.

It will thus be possible to obtain from these two sources—that is, The Adjutant General and the Provost Marshal General—a complete medical military census of the men of draft age in this country.

The division of medical history occupies space in the Surgeon General's Office for its routine work and for cataloguing and filing the materials which are of current or frequent use. Space for the safe storage of massive materials is provided in the Surgeon General's museum and library.

Those who are familiar with the conditions under which the materials for the Medical and Surgical History of the Civil War were obtained will recognize a great advantage in the organization of the historical purpose very early in the present war. The medical records of the Civil War were available only at the discretion of The Adjutant General. The medical records of the Provost Marshal General were not available.

Under present conditions the Surgeon General will have possession and use of all medical and surgical records, including those of The Adjutant General's Office and the Provost Marshal General's Office under the conditions as stated above.

XXIII. Army Medical School.

Owing to the increase of the Army and the large number of existing and prospective vacancies in the Medical Corps occasioned thereby; the addition to the regular course of an elaborate course in orthopedic surgery; large successive classes of enlisted men receiving instruction in laboratory technique, for detail to base hospitals, stationary and mobile laboratories; it has been found necessary to make further provision for these increased activities. To accomplish this end the adjoining premises at 458 Louisiana Avenue have been rented and fitted up as office rooms, metal and woodworking shops, plaster band-age shop, miscellaneous laboratories, drafting rooms, and classrooms. To further accommodate the activities of the school the premises at 472 Louisiana Avenue have been leased and will be ready for occupancy by July 1, 1918. This latter building will be occupied by the orthopedic section of the school, while the building vacated by this section will be given over to the personnel officer, the property officer, and the commanding officer, Army Medical School Detachment of the Medical Department.

TWENTY-FIRST SESSION.

The third section began August 1, 1917, and ended October 4, 1917.

TWENTY-SECOND SESSION.

The first section began November 12, 1917, and ended February 2, 1918.

The second section began March 11, 1918, and ended June 15, 1918.

The number of accepted candidates appointed in the Medical Reserve Corps and ordered to the school for instruction in the regular course was 186. Of this number 9 elected to pursue the orthopedic course, one of whom was relieved from attendance and ordered to his home by reason of physical disqualifications before the completion of the course.

No members of the Organized Militia attended either section.

The postgraduate course for officers of the Medical Corps was not given; however, one first lieutenant, Medical Corps, attended one of the classes in orthopedics.

Of the 177 student candidates who completed the regular course of instruction, 172 qualified at the final examinations. Of this number, 169 were recommended for commission in the Medical Corps, 3 failing to receive such recommendation because of deficiency in general aptitude for the military service.

Each of the 8 student candidates who pursued the orthopedic course was graduated, 7 of them being recommended for commission in the Medical Corps, 1 failing to receive such recommendation because of deficiency in general aptitude for the service.

The number of Medical Reserve Corps officers ordered to the school for the course in orthopedic surgery and not candidates for commission in the Medical Corps was 53. Of this number 1 was found physically disqualified and ordered to his home; 18 were relieved from duty at the school before the completion of the course and sent overseas and to hospitals and training camps throughout the country for the purpose of instructing in orthopedic surgery; 28 qualified in the final examinations and were graduated from the school; 2 of these later took the preliminary examination and were recommended for commission in the Medical Corps.

One officer of the Medical Corps and one surgeon, United States Navy, attended the course in orthopedic surgery.

The third section of the twenty-second session will commence about July 10, 1918.

The section of orthopedic surgery of the Army Medical School was established November 12, 1917, and has been housed, up to June 30, 1918, in the building adjoining the main school building, at 458 Louisiana Avenue. This section provides a course of instruction in the theory and practice of orthopedic surgery for certain student officers in attendance at the Army Medical School, and certain other medical officers ordered to the school for this purpose.

Besides the offices and classrooms the orthopedic annex is provided with shops and laboratories equipped with a motor-driven lathe, combination hand punch and shear, bench drill, motor-driven emery grinder, work benches, laboratory tables, appliances for the application of plaster bandages and dressings, etc.

In addition to the commissioned personnel there is assigned to this section an enlisted personnel of 36 men, through whose equipment and qualifications the section is capable of serving a new and most useful function, aside from that of a teaching institution, namely, that of a mechanical unit for such experimental, developmental, and repair work as might be required, not only by the division of orthopedic surgery, Surgeon General's Office, but by the Medical Department as a whole.

During the past year a number of officers of the Medical Reserve Corps and Sanitary Corps have been sent to this school from the Rockefeller Institute for Medical Research for additional laboratory instruction. Approximately 150 officers received this instruction. This course is of one month's duration and is given each month. The course embraces the following subjects: culture media, bacillus typhosus, bacillus paratyphosus "A," bacillus paratyphosus "B," isolation and identification from stools, dysentery bacillus, meningococcus, pneumococcus, standard agglutination method, anaerobes, staining of tubercle bacillus, gonococcus, malarial parasites, and intestinal parasites.

Enlisted men of the Medical Department, some of whom are sent here, and others enlisted at the school for the purpose, are given training in laboratory technique. These men are grouped in three classes: the beginners' class of laboratory technicians, the advanced class of laboratory technicians, and the class of X-ray technicians.

The beginners' class of laboratory technicians receives instruction in the cleaning of glassware, sterilization, the use of the microscope, routine stains, in the bacteriological laboratory. This course is of two months' duration and is given every two months.

The advanced class of laboratory technicians receives instruction along the same lines as the regular officers' class in the bacteriological laboratory, with the addition of staining the gonococcus, tubercle bacillus, and the examination of urine. This course is of two months' duration and is given every two months.

Half of the time of these two classes is spent in the chemical laboratory, where they receive practically the same instruction as is given the regular officers' class, special topics in volumetric analysis and certain laboratory methods of the Medical War Manual No. 6, and the sanitary analysis of water and sewage.

Four hundred and thirteen men received instruction in these classes. Of these men 30 have been commissioned as second lieutenants in the Sanitary Corps, and 37 more have been recommended for commission as second lieutenants, Sanitary Corps.

The class of X-ray technicians is given lectures and practical laboratory instruction in X-ray technique, embracing the construction and operation of X-ray machines in general, wiring, coils and interrupters, tubes, current, plates and developing, fluoroscopy, localization of foreign bodies, osteology, etc. These men, upon completion of the course of instruction, are given further practical experience by working in the X-ray laboratories of the Army Medical School, United States Soldiers' Home Hospital, Walter Reed General Hospital, Georgetown University Hospital, George Washington University Hospital, Children's Hospital, Episcopal Hospital, and Providence Hospital. Ninety-nine enlisted men took this course, of whom three have been commissioned in the Sanitary Corps.

A special short course of instruction, in the form of lectures, was given to a group of transport surgeons ordered here for this purpose. These lectures covered, in a brief way, the following subjects: general and military surgery, head surgery and surgery of the nervous system, amputations, Medical Department administration, insanity and functional neuroses, deafness and speech defects, blindness, tuberculosis, and paper work. The lectures were given by members of the faculty of the Army Medical School and officers of the Medical Reserve Corps on duty in and about Washington.

This report would be very incomplete if it did not include a summary of the activities in which the Army Medical School is engaged aside from its functions as a teaching institution.

Briefly, these activities are summarized under the various heads as follows:

During the year just closed the mobilization of the National Army has required an enormous production of vaccine. This production has gone forward without delay, which reflects great credit on the officers and enlisted men engaged in the work. Not only has the quantity produced been adequate at all times, but the requirement for additional glassware and new laboratory installations and apparatus have been met with no interruption, and vaccines have been packed and shipped, so far as practicable, within 24 hours after receipt at the school of the requests.

Over 15,400 liters of vaccine, more than 18,000,000 doses, have been shipped during the fiscal year. This is believed to be a record for all laboratories at any time, including the present war. The cost value of the vaccines manufactured at the school during the year was approximately $900,000. For the commercial vaccines, this represents a retail market value of $4,500,000, a saving to the Government of approximately $3,600,000.

During the year the method of suspending bacterial vaccines in oil has been tested and reported on, and the triple typhoid vaccine suspended in oil is being adopted by the Surgeon General's Office. It is understood that as rapidly as the machinery for production is available the oil-suspended vaccine will replace the saline triple typhoid vaccine.

An oil-suspended dysentery vaccine has been tested and has given evidence of protection. The Surgeon General's Office expects to try this vaccine on a large scale during the coming summer.

The pneumococcus vaccine suspended in oil has been tested and has given definite evidence of protection against pneumococcus Types I and II.

Oil-suspended vaccines of the meningococcus, streptococcus, and cholera vibrio have been tested, but the tests have not yet produced far enough to enable us to express an opinion of the value of these vaccines.

The Wassermann reaction has been performed continuously as a diagnostic test for syphilis. During the year ended June 30, 1918, the total number of Wassermann tests in the laboratory was 19,524, of which 531 were reexaminations; 16,532 were also made in accordance with existing orders calling for a Wassermann reaction on applicants for commission, enlisted candidates for various service schools, recruits, etc.; and 2,461 examinations of new cases. Of the latter, 1,280 were of syphilis or suspected syphilis, and 1,181 were from cases suffering with diseases other than syphilis. In addition there were 681 tests made for gonococcus fixation, 242 spinal fluids in three dilutions. In addition to this there were 681 gonococcus fixation tests performed. These at ordinary commercial rates of $5 per test would have cost the Government $101,025.

A liberal estimate of the cost of this work, including the salaries of one lieutenant colonel, one captain, and one sergeant, is only $8,836. This item alone represents a saving to the Government of $92,189.

The chemical laboratory has received and reported the analysis of 137 various substances, and has examined 14,635 specimens of urine. The chlorination and purification of certain substances used in connection with dichloamine T was undertaken during the past year. To date there have been produced 105 liters of chlorinated eucalyptol, 373 liters of chlorinated mineral oil, and 223 pounds of chlorcosane. A comparison of the actual cost of production of these products and the lowest market price follows:

	Market price.	Cost of production.
Chlorinated mineral oil (per liter)	$3.07	$0.87
Chlorinated eucalyptol (per liter)	9.92	3.53
Chlorcosane (per pound)	2.00	.45¼

The laboratory has been unable to produce these materials of dependable purity and has effected an estimated saving of $1,835.

A bank of 40 stills for water analysis has been designed and is being built to take care of the increased demand of the classes.

In addition to the teaching work the X-ray department has done a large amount of work in the form of examinations and treatment for the officers and enlisted men and their families stationed in and near Washington.

The X-ray laboratory has been remodeled to a certain extent, the photographic branch being moved to the sixth floor, where photographic reproductions and photomicrographs are made and lantern slides prepared. More privacy has been given to the plate-examining room, in which have been installed special illuminating boxes and special facilities for the cataloguing of plates. An additional room has been provided for the examination of teeth and extremities. The former photographic room has been converted into an additional operating room for instruction.

This department has aided in the designing and completing of an X-ray ambulance for the United States Army portable X-ray unit. The ambulance has been driven to Ontario, Canada, where it was demonstrated for the benefit of the Canadian Government.

The portable field outfit, the portable bedside unit, and numerous other new pieces of apparatus, were tested out in conjunction with the duties of the laboratory. Various intensifying screens, photographic plates, and X-ray accessories were tested out and results reported.

The conducting of physical examinations at this school has become a function of ever-increasing magnitude. The scope of the work has been broadened so that it not only includes the physical examinations of officers for promotion and of applicants for the various Officers' Reserve Corps, but also for the determination of the physical fitness of officers for overseas service and the examination of men inducted as privates in the Medical Department.

The board is fortunate in having all the modern equipment at hand necessary for performing a most thorough physical examination, and in physical conditions of unusual obscurity medical officers highly skilled in medical and surgical specialties are called in consultation. As a result, all physical examinations are conducted along routine and well-established lines with a maximum of accuracy and expedition.

The number of physical examinations made average approximately 750 per month, and ample facilities are provided to handle twice this number, should the need arise, without in any way affecting the standard of the examinations made.

A large number of Medical Reserve Corps officers are sent through the Army Medical School, preparatory to service overseas. The school assumes entire charge of them, giving instructions as to uniform, equipment, personal reports, insurance, money affairs, etc. Here they are vaccinated against typhoid and paratyphoid fevers and smallpox, are physically examined, and, at the proper time, reported ready. When orders arrive for them, these officers are furnished with true copies of same, with adequate instructions for carrying them out. This work comes under the head of "Foreign Service Department," and is very successfully taken care of through a card-index system, and is handled in the office of the chief clerk.

Here, also, are indexed each member of the faculty, the student officers, every officer ordered here for duty or station, all the civilian employees, and all of the enlisted men. The officers and men, upon reporting at the school, are registered, sufficient data to identify each man being recorded; the date of departure and destination are noted on each card, after which the card is placed in the dead file, where it becomes an index for guidance in sending subsequent communications and forwarding mail. The monthly return of medical officers is made, the records and marks of the student officers computed, and the merit rolls and the relative proficiency lists (which become a part of this report) are prepared in this office.

The printing department of the school has grown to rather large proportions, the personnel and apparatus of this plant being frequently taxed to its utmost. Examination questions for entrance to the Medical Corps, Dental Corps, Veterinary Corps, and the Medical Reserve Corps, examination questions for the final examinations at the school, bacteriological and chemical technique cards, bulletins, miscellaneous cards and blank forms for use at the school and labels for all the vaccines shipped from the school are among the many varieties of work turned out in this department.

During the year the total number of prints made was 1,518,100, including 15,100 sheets of examination questions. The preparation of these questions involved the folding of these sheets and the sealing of 17,161 envelopes.

In connection with the printing department, one man, a private, first class, Medical Department, is employed in illustrating and in engrossing diplomas and other certificates and charts.

The following exhibits the course of instruction: military surgery; military hygiene; bacteriology, pathology, and laboratory diagnosis; military and tropical medicine; medicine department administration; ophthalmology; roentgenology; sanitary chemistry; sanitary tactics; shoes and feet; shop work; plaster work; clinical work; anatomy and operative surgery.

A course in elementary French has been added to the curriculum of the school in the past year. This instruction is given by a civilian, a native Frenchman, who is paid by individual subscription of members of the class. While this course is not compulsory, most of the student officers have availed themselves of it and have been much benefited by it.

During the year a number of special lectures were given, including a series by Col. Goodwin, of the British Royal Army Medical Corps, now Surgeon General of the British Army, covering the work of the British officers under field conditions in the trenches, and of the field ambulances, including descriptions of evacuations of the wounded, gas attacks, etc. Col. Dercle, of the French Medical Corps, delivered a very useful and instructive lecture on "Field Service with the French Armies;" Maj. Opie, of the Medical Reserve Corps, one on trench fever; Maj. Albee, Medical Reserve Corps, on bone transplantation; Maj. Salmon, Medical Reserve Corps, on war neuroses; Dr. Simon Baruch, on gudrotherapy; and Dr. Case, on gastroenterological work from the X-ray standpoint. Some of these lectures were illustrated with motion pictures and lantern slides.

The recommendation is renewed that the present makeshift, scattered buildings be replaced by special, permanent buildings, to be constructed in grounds of sufficient extent to make it possible to put the classes in barracks, and part of the time in camp, to give the students a place to drill, to be instructed in field work, practical sanitary tactics, equitation, etc. It is to be hoped that the facilities will be provided to make the Army Medical School a postgraduate institution, with all the necessary equipment and facilities for teaching everything necessary, including field work, to make Army medical officers out of selected graduates of medical schools.

In normal times the course will probably be extended again to eight months, and with increased accommodations and facilities and good drill and camping ground very large classes can be instructed in all the special duties of Army medical officers, and at the same time the laboratories can be utilized as at present, but on a much more extended scale, for research work, clinical diagnosis, sanitary chemistry, X-ray work, and the manufacture of all sera, vaccines, and antitoxins for the Army.

XXIV. THE AMERICAN RED CROSS.

(NATIONAL HEADQUARTERS, WASHINGTON, D. C.)

During the past year the American Red Cross has endeavored to assist the Medical Department in every way that was deemed desirable in the care of the troops of the United States, whether in camp, cantonment, or hospital, both in the United States and abroad. The work, outlined as follows, was authorized by the War Department:

There were organized throughout the country 50 base hospitals, all of which originated in the large hospitals or medical schools, and from these institutions many of the leaders in the medical profession were obtained as members of the staffs of these base hospitals.

There were also organized 45 ambulance companies: all of these were transferred to the Medical Department of the United States Army. These companies were organized in the various communities from Maine to California.

The department of military relief has been actively interested in the problem of reeducation of crippled soldiers and, as authorized, has established in New York an institute for crippled and disabled men where the reeducation of cripples is now being conducted, utilizing the institute for civilian cripples until such time as it may be needed for crippled soldiers. This institute has also instructed classes of vocational teachers, who can be used hereafter in such institutions as the Government may establish in connection with its program of reeducation.

An institute devoted especially to the blind has been organized in Baltimore, which expects to cooperate with the efforts of the Medical Department in the reeducation and the replacement of all the blind soldiers on their return to the United States.

The bureau of sanitary service of the department of military relief cooperates with the Surgeon General's Office, the Public Health Service, and the local health authorities in the extra cantonment zones in order to protect the military forces in the camps from contagious and infectious diseases present in the immediate surroundings of these camps. In a number of the southern camps work has been undertaken to eradicate the possibility of mosquito transmission of malarial infection. Systematic inspections are carried out of dairies, milk depots, restaurants, and all places where food or refreshments are sold. Clinics have been established in practically all the extra cantonment zones for the treatment of carriers of venereal infection, with the idea of eliminating these diseases at the source of origin. In this work the Red Cross has cooperated with the training camp activities commission and the local authorities, being greatly assisted by the recent legislation which has been passed in practically all the States in the Union aimed at assisting in this campaign of prevention. Four laboratory cars were prepared by the Red Cross, using old Pullman cars and having them completely outfitted with all the modern apparatus necessary to conduct a modern laboratory. From the beginning the work of these cars was so obviously successful that the Surgeon General's Office requested the transfer of three of them to his department, which was done.

The first-aid division of the American Red Cross has continued the work which has been carried on in previous years in its campaign of education and instruction along first-aid and accident-prevention lines and has tremendously increased the scope of its work. The main idea, at the present time, is to disseminate this first-aid instruction, so that with the withdrawal of many nurses and physicians from civil life the general public will be better fitted to care for their own health without professional assistance.

Working in very close connection with the office of the Surgeon General of the Army, a number of orders have been received from the Medical Department of the Army for surgical dressings and hospital garments for use both in this country and abroad. The Medical Department has furnished the raw materials and the Red Cross has had them made up by volunteer workers in its various chapters in accordance with the approved standards.

In France the American Red Cross has enormous warehouses containing large stocks of surgical dressings, hospital garments, and supplies. These have at all times been at the service of the chief surgeon of the American Expeditionary Force, but the records for the amount of supplies delivered over there are not available at this time here.

The largest single order placed with us was for front-line packets, to be delivered in regular installments. Up to the present time there have been delivered on account of this order over 900,000 parcels in three different sizes, each parcel containing from 8 to 16 dressings, depending upon its size. In addition there have been delivered more than 2,000,000 various other dressings.

The Red Cross has endeavored to meet every demand for hospital garments which we have been asked to furnish to the Surgeon General's office, and up to this time we have delivered various kinds of chapter-made hospital garments, amounting to about 100,000.

In compliance with the request of the Secretary of War, contained in his letter of January 26, 1918, addressed to Mr. Davison, the Red Cross has extended the communication service which it is doing abroad to the Army hospitals in this country. Representatives have been placed in the base and general hospitals, and it is their duty to supplement the communication service rendered by the Army officers to such extent and in such a manner as shall meet with the approval of the officers. These Red Cross representatives visit the wards daily and undertake to keep in constant touch with all of the patients. They provide writing materials for men who wish to write letters. They write letters for such men as wish to communicate with their families and can not write for themselves, and keep the families advised of the progress of very ill patients. The extent to which this service has developed in any given hospital depends to a very large extent on the wishes of the commanding officer and varies considerably in the different hospitals. Taken as a whole the service has rapidly grown to large proportions and the volume of correspondence is now considerable. The service rendered very often helps to relieve the mind of the patient and in this way helps his recovery, and, on the other hand, the receipt of letters by the families from a disinterested source, advising them of the progress of the patients and assuring them that they are receiving the best of medical attention, does much to quiet rumors of inefficiency and lack of proper care of enlisted men. This is shown by the steady stream of letters the Red Cross receives from families expressing thanks for the letters and the interest the Red Cross is taking in the boys.

The Red Cross has undertaken to erect convalescent houses at all of the base and general Army hospitals in this country, which are intended as a place of recreation for the convalescent patients of the hospitals. A standard plan of these buildings in two sizes has been carefully prepared and has been approved. Up to the present time contracts have been signed for the erection of 48 of these buildings at the Army hospitals and over 20 of these buildings have been completed and are now in operation.

While these buildings are intended primarily for the use of convalescent patients, they are available for such service as the officer in command may desire. These buildings include a number of bedrooms, which will be available for the use of relatives of men who are on the danger list in cases where the commanding officer desires that such relatives shall stay at the hospital over night. A small kitchen is included, which will make possible providing food for such visitors, and also possibly for such Red Cross personnel which it may prove necessary to maintain in the building.

In some cases these buildings have been used as an information office where visitors to the hospital can see patients, secure information concerning them, arrange for passes to visit the wards, etc. In some of the camps this branch of service has developed to such an extent that it has proved necessary to erect a separate building in which the information service can be carried on in order that the constant stream of visitors will not interfere with the use of the convalescent buildings by the convalescents themselves. This has occurred in cases where the camps are located near large cities, from which there has been a constant stream of visitors.

Home service has been undertaken to assist in maintaining the morale of our fighting forces by extending assistance to the families of enlisted men to preserve the essential standards of home life, to meet the problems arising out of diminished income, sickness, care, discipline and education of children, household management, business and legal difficulties, unsatisfactory working conditions, loneliness, mental depression or defect, vice, or physical disability.

The emergency service in this country, as in the seat of war, is ready to respond to any call which may come from the officers of the Army to render emergency service of any kind whatsoever. Medicines and hospital equipment of various kinds have been provided in many places to meet urgent needs.

At the request of the Surgeon General, two Ford touring cars and one Ford truck were donated to each of six different base hospitals. The Red Cross has also donated a number of other automobiles from time to time to hospitals in different parts of the country in response to requests received from commanding officers in cases where there was a shortage of transportation facilities. These automobiles have been used by the hospital staff to enable them to render more efficient service.

The associate field directors in charge of hospital service have been called on to perform a great variety of different kinds of service for the patients and errands of every description have been undertaken.

At some of the camps classes for patients have been arranged, ranging from primary grades for illiterates to classes in French, which have been taught by regular teachers from near-by schools, and the patients have been interested in various sorts of handicraft, especially in the psychiatric wards.

In order to administer the activities above outlined efficiently, it has been found desirable to place an associate director in charge of hospital service at each of the base and general hospitals. This representative of the Red Cross is accredited to the commander of the base hospital in accordance with the provisions of General Order No. 17 and is responsible to the commanding officer for all Red Cross activities conducted in the hospital. In order to administer the communication work efficiently it has proved necessary to provide several assistants for the associate director.

The nursing personnel of 52 base hospitals has been organized. In the early days of the war these were increased from 65 to 100 nurses. Twenty-one hospital units have also been organized with a nursing personnel of 21 nurses each. The nursing personnel of 6 special hospital units was entirely or partially organized, the deficiencies being supplied from the cantonments or from the members of the Regular Army Nurse Corps. These include the orthopedic unit, the head and neck surgery unit, the fracture unit, the psychiatric unit, Reconstruction Hospital No. 1, and a mobile operating unit. The personnel of all these units has been assigned to duty either abroad directly or to the cantonment hospitals.

The total number of nurses supplied to the Military Establishment since the declaration of war to the first day of July, 1918, has been 10,438. Of these, 546 were assigned previous to June 30; 92 for the Mexican border, and the remainder were attached to 7 base hospitals assigned prior to June 30, 1917, for foreign service.

All nurses assigned to foreign service, not only as members of the Red Cross Reserve, but as members of the Regular Army Nurse Corps, have been supplied by the Red Cross, at an approximate cost of $200 per nurse, with uniform and other personal equipment. The dietitians and clerical workers assigned to service with the base hospitals have also been equipped at approximately the same cost.

The names of 31 nurses, highly qualified, with administrative experience, have been recommended to the office of the Surgeon General for appointments, in order to prepare for the examination as chief nurse. It is understood that these nurses enter the Regular Army Nurse Corps for the period of the war.

XXV. PORT OF EMBARKATION, HOBOKEN, N. J.

The Medical Department at the port of embarkation was first represented by a medical superintendent. He had one assistant and one clerk. He was directly under the general superintendent, Army Transport Service, and his activities were very limited. Under the existing circumstances it was almost impossible to discover and remedy any unsanitary conditions, although such conditions did exist. The immediate need was the medical supply and equipment of the few transports available and the assignment of sufficient commissioned and enlisted personnel to perform the duties of the Medical Department aboard same.

When the office of the surgeon, port of embarkation, was established supervision of the duties of the Medical Department, Army Transport Service, were also assumed. After the first survey of the situation the personnel on duty was deemed insufficient in number and one of the first steps of the surgeon was to surround himself with efficient commissioned and enlisted personnel who would, as it were, grow up with the office, thereby anticipating the growth of the port of embarkation.

PERSONNEL DIVISION.

In June, 1917, the first convoy of United States troops was sent to France, which necessitated the assignment of certain medical personnel, both commissioned and enlisted, for duty on transports. These, in addition to the personnel on duty in the office of the medical superintendent, Army Transport Service, formed the nucleus of the present organization known as the office of the surgeon, port of embarkation. Being directly under the control of the War Department, it was necessary for this office to assume the duties of a department surgeon. To that end the duties relating to personnel were divided into two sections, i. e., those relating to personnel assigned for duty, called the permanent personnel division, and those passing casually through the port, known as casual personnel division. Each of these was under the direction of a noncommissioned officer, while the two divisions were under the control of a commissioned officer.

TRANSPORT DIVISION.

This division was the office of the medical superintendent, Army Transport Service, and embraced his duties as laid down in transport regulations, and has been known under various names—first, office of medical superintendent; second, sanitary division; third, transport division.

Primarily the duties of the medical superintendent were to act as sanitary inspector for the port of embarkation; supervise the administration of Medical Department activities on board transports; make and cause to be made required embarkation physical inspections; provide for the reception and care of military persons unable to travel; provide necessary supplies and equipment for the transport hospitals; provide sufficient medical personnel for the proper care of the sick aboard same; to obtain necessary information in regard to movement of troops and transports. Most of these duties have been delegated to or assumed by other divisions of this office, to wit:

Supervision of Medical Department administration and detail of medical personnel aboard transports—to the personnel division.

Duties of sanitary inspector—to the sanitary inspector's division.

Provision for reception and care of military persons unable to travel—to the sick and wounded division.

Provision of necessary supplies and equipment for transport hospitals—assumed first by the property division and later by the transport supply division.

Acquisition of information in regard to movements of troops and transports—to the liaison officer.

As now organized, the duties of the transport division are as follows:

Supervising the embarkation of troops, conducting preembarkation physical inspections, disposing of such cases as are detained at time of embarkation; proper and timely designation of medical officers to perform above duties; supervising debarkation of sick and wounded until such time as they are turned over to sick and wounded division, keeping necessary records of the division.

Personnel on duty, commissioned 53, enlisted 10.

During October communication was received to the effect that many venereal cases were arriving overseas and recommending that measures be adopted to check same. The first venereal inspection was made on October 15, 1917, on trains bearing the Third United States Cavalry. Nineteen cases were removed. Then followed venereal inspection of all troops for overseas in accordance with General Order No. 21, headquarters, port of embarkation, October 22, 1917.

Following the first preembarkation venereal inspection routine inspections were made, but for venereal diseases only. During the early winter the advent of the communicable disease season brought further to the attention of the surgeon, the need of more extensive physical inspection, and General Order No. 3, January 8, 1918, headquarters, port of embarkation, and General Order No. 51, May 18, 1918, headquarters, port of embarkation, were made and included measles, mumps, cerebrospinal meningitis, scarlet fever, etc. By this time the sailings had increased and more inspectors were added to the division.

FINANCE DIVISION.

This division was established when the office of the surgeon was first organized. The principal duty was the purchase of supplies.

Later it was incorporated with the property division, and when the growth of the office required same, it was again instituted as a separate division under the control of the executive officer. The correspondence and files divisions were also included in the division at this time merely for the purpose of administration.

In December, 1917, the finance division was separated from the correspondence and files divisions and entirely reorganized.

ATTENDING SURGEON'S DIVISION.

Shortly after the port of embarkation was established some certain place for the medical and surgical treatment of military persons on duty here was needed. A dispensary being shortly established an attending surgeon was appointed and placed in charge thereof. Increase in the personnel on duty at the port of embarkation necessitated the assignment of additional personnel, and for administrative purposes the office of the attending surgeon was absorbed by the office of the surgeon, port of embarkation, and made a separate division to be called attending surgeon's division.

Increase in the jurisdiction of the commanding general, port of embarkation, made it necessary to establish certain first-aid and prophylactic stations, and they were placed under the control of this division.

SICK AND WOUNDED DIVISION.

In October, 1917, this division was established for the purpose of checking and forwarding sick and wounded reports of the various organizations under the control of these headquarters. This was placed in charge of a noncommissioned officer and under the supervision of the chief clerk.

Anticipating the growth of the port of embarkation and the probable return of large numbers of sick and wounded from overseas, the division was reorganized in December, 1917, and placed in charge of a commissioned officer. As organized, the duties are as follows:

THE ADMINISTRATIVE SECTION.

Conducts all correspondence relative to the sick and wounded division.

Adjusts bed capacities in the embarkation hospitals by timely transfers of patients.

Arranges all transfers of overseas patients from the port to the service of the interior.

Directs disposition of patients with contagious and communicable diseases.

TRANSPORT SUPPLY DIVISION.

This division was organized in February, 1918, to arrange for a systematic medical supply of transports. Prior to that time transports were supplied through the transport and property division. Owing to the small number of ships engaged in this work almost no attention was required to supply them, but as the number of ships increased, it was deemed necessary to have an efficient organization for this purpose.

The division was organized and assumed control of the medical supply of transports. No system of supplying being in effect, some time and study was allotted to standardizing the amount and variety of supplies and equipment according to the number of troops carried. The plan adopted has been in operation for over four months and so far is satisfactory. In April the Surgeon General authorized the employment of ship's surgeons (civilians) of commercial vessels carrying troops, to perform certain services, to be paid from the Medical Department appropriation. This division being in direct contact with the persons concerned, the duties connected with the procurement of services and preparations of vouchers, etc., were assigned to it.

From a force of 1 commissioned officer and 1 enlisted man the personnel of the division has been increased to 2 commissioned officers and 14 enlisted men.

SANITARY INSPECTOR'S DIVISION.

This division was established for the purpose of making the various sanitary inspections at the port of embarkation, which are required by War Department orders and other regulations.

Due to the increase in the personnel of this port and the large amount of troops embarking for overseas, the transport division could not properly perform its allotted duties. It was necessary, therefore, to assign some of them to another division. The sanitary inspector's division being already established, it was decided to allot the sanitary inspection duties, except those concerning the inspections of troops as required by general orders, headquarters, port of embarkation, to this division.

As originally organized and with its added duties, the functions of the sanitary inspector's division are as follows:

Sanitary inspections of all buildings, camps, piers, transports, etc., under control of these headquarters.

Fumigation.

Physical inspections of troops stationed at port of embarkation.

HOSPITALS AND CAMPS.

Sanitary inspections of the hospitals under the authority of the port of embarkation are carried on daily, Sunday excepted. One officer is detailed for this work. A list of the hospitals visited, with the date of inspection, is made of record. Sanitary deficiencies of note are made the subject of special report, which is forwarded by this office to the Surgeon.

A monthly report of Camp Merritt and of Camp Mills is made. Reports of same are made of record.

Detachments under the jurisdiction of these headquarters are inspected twice a month, or oftener, if necessary.

SHIPS.

The following classes of ships are inspected by this office:

United States Army troop transports.

United States Army chartered cargo transports,

Commercial troop ships carrying United States troops.

Immediately upon the arrival of a ship belonging to the above classes, a sanitary inspection of this ship is made, and all deficiencies noted. This is made in the form of a report to higher authorities, with appropriate recommendations for correction. Before the departure of these ships another inspection is made with the view to checking up the degree to which deficiencies have been corrected. The second report is forwarded through the same channels.

FUMIGATION.

This office has charge of the fumigation of ships and buildings under the authority of these headquarters.

SPECIAL INSPECTIONS.

Conditions calling for special sanitary inspections are referred to this office.

The duties of this office have increased quite rapidly, due to the addition of a large number of commercial troop transports for the transportation of our troops abroad. The personnel has been increased from two commissioned medical officers to seven commissioned medical officers and five enlisted men. This office has enjoyed full cooperation of other offices under these headquarters and those of the British Ministry of Shipping.

The work of this office has to a great extent been hindered by the inability to have boat transportation always available when needed. The inspection of incoming troop ships is most important in view of the fact that many of them are not fitted to carry troops, and will not be so fitted until proper recommendations relative to equipment have been made. It is most essential that these recommendations be promptly made in order that the ships may be equipped before sailing, which in most cases is only a few days.

LIAISON OFFICER.

Prior to March, 1918, it was difficult for the different divisions to obtain the information regarding movements of troops and transports necessary to properly perform their duties. Relief was imperative and to that end a commissioned officer was appointed to maintain a liaison between this office and the different departments at these headquarters. Satisfactory results are being obtained. At present there is on duty in this division one commissioned officer.

TRANSPORTATION DIVISION.

Since this office was organized it has been one of the duties thereof to transport ever-increasing numbers of sick and wounded. First this was accomplished by the ambulance division, which was a separate division of this office, controlled by a noncommissioned officer, who was directly responsible to the surgeon, port of embarkation.

Owing the wide distribution of the various hospitals, it was necessary to obtain transportation from the local companies in the form of tickets. These were requisitioned for and issued by the property division, who also accounted for same.

In order to coordinate the different methods of transportation and eliminate any chance of misuse of same, it was decided to institute a new division, namely, the transportation division, whose functions would be that of directing the transportation of men and supplies, in so far as the Medical Department was concerned.

HOSPITAL DIVISION.

This division was organized in May, 1918, for the purpose of procuring suitable buildings in this vicinity for hospital purposes. There are five commissioned officers and two enlisted men on duty therein.

On May 23, a representative body of real estate men, all members of the Real Estate Board of New York, met and organized for the purpose of lending their aid, and as a result there was formed an advisory committee for this division.

Altogether more than 12,000,000 square feet of floor space have been surveyed, of which some 7,000,000 have been recommended or secured, and the balance classified as not available or not suitable.

The work of this division will soon be completed, and the personnel on duty therein will be assigned to another division.

DIVISION OF DENTAL SERVICE.

This division was organized in July, 1918, to meet the need of adequate dental supervision at the port of embarkation.

DIVISION OF LABORATORIES.

This division was established in July, 1918, for the purpose of centralizing laboratory facilities and the supervision of laboratory work at the port of embarkation.

DIVISION OF DOMICILIARY HOSPITALS.

Many offers of homes for convalescent soldiers having been made to the Surgeon General of the Army, and the surgeon, port of embarkation, it was decided to make use of these offers as far as possible. To that end it was decided to establish a division of this office for the purpose of organizing and supervising a system whereby these places would be used.

At present there are in use six places, with a capacity of 186 patients. Fourteen other homes, with a capacity of 1,498 patients have been offered, but have not yet been accepted for use.

Having given a history of the office by divisions, it will be well to revert to the time when the office was established, and take up the question of hospital accommodations.

When the port of embarkation was established, no provision had been made for hospital treatment. The port hospital at Port Jay was used for a time, also a civilian hospital, St. Mary's, in Hoboken, N. J. Arrangements were made with the proper authorities and 500 beds at St. Mary's Hospital were made available to the military. This hospital was designated as the hospital, port of embarkation, now known as Embarkation Hospital No. 1.

The base hospital at Camp Merritt was in the process of construction when the camp was occupied, and an overflow of sick necessitated the use of civilian hospitals. The ambulance at Snake Hill, Secaucus; Christ Hospital, Jersey City; Isolation Hospital, Jersey City; North Hudson Hospital, Weehawken; and Englewood Hospital, Englewood, N. J., were used until recently.

The almshouse at Snake Hill has been designated as an Army hospital, and is now known as Embarkation Hospital No. 2. In October, when the War Department ordered the detention of venereals, the New York State authorities placed the quarantine station at Hoffmans Island at the disposal of the Government, and the station was used for the treatment of venereals. Designated as Army hospital, Hoffmans Island, it is now known as Embarkation Hospital No. 3.

About the same time the hospital at Camp Mills became congested with sick, and in order to relieve conditions, all available beds in New York district were placed under the control of the surgeon, port of embarkation. He was also charged with the disposition of all patients. Due to lack of Army beds use was obtained of various civilian hospitals in New York City and Long Island. These were used until January, 1918.

When Camp Mills was reopened, spring of 1918, a base hospital was established at Mineola to care for the needs of the camp. Schuetzen Park, North Bergen, N. J., estimated capacity 300 beds, and the Greenhut Building (Debarkation Hospital No. 3), estimated capacity 3,000, are being prepared for service. Other hospital space has been or is being obtained.

PROVIDENCE HOSPITAL.

The act approved June 12, 1917, having appropriated $19,000 for support and medical treatment of destitute patients in the city of Washington, D. C., under a contract to be made with Providence Hospital by the Surgeon-General of the Army, for relief afforded was as follows:

Patients in hospital July 1, 1917	74
